Dr. Alexander H. Peacock, Seattle: We have tried hexylresorcinol in a limited number of cases, but there are certain things against it: its cost and the long period of time over which it must be taken makes it prohibitive for many patients. The druggists have got hold of it, advertise it as a very efficient remedy and get exorbitant prices for it. In the very limited way in which we have used it, I do not think we have had any better results than from other urinary antiseptics, and it does cause irritation in a large percentage of the cases.

Dr. Daniel E. Shea, Hartford, Conn.: One of my greatest objections to hexylresorcinol is its cost. Many of our clinic patients cannot afford it at its present price. I cannot say that I have seen any remarkable results after its use. One patient developed a severe hematuria after its use, while another patient complained of severe gastro-intestinal disturbances. I, also, have been prescribing plenty of fluids. If fluids are contraindicated while taking hexylresorcinol, I shall eliminate the drug and give the fluids. I feel that they are very necessary in the treatment of urologic conditions.

Dr. Leon Herman, Philadelphia: In Dr. Leonard's original paper on hexylresorcinol, it is stated very definitely that the drug has proved most useful in the treatment of superficial infections of the urinary tract. In fact, attention is drawn to its inability to influence infections within the renal parenchyma, the prostate gland and other structures far removed from the lining mucosa of the urinary passages. If we eliminate this type of case, there are comparatively few cases in which hexylresorcinol would be of service, for uncomplicated surface infections of the mucous membrane are relatively uncommon. Many of the cases reported by Drs. Lowsley and Henline were instances of what in all probability were deep seated infections; notwithstanding this fact, the infection disappeared more or less promptly under treatment with hexylresorcinol. This is in direct contradiction to Dr. Leonard's original conception of the action of the drug. It is difficult to understand how one could eliminate infection from a kidney filled with stones; certainly it could not be accomplished by any means other than hexylresorcinol Dr. Lowsley has shown several instances of this kind, and the conclusion would seem to be inevitable that hexylresorcinol will cure not only superficial infections but deep seated ones as well.

Dr. Lionel P. Player, San Francisco: I have used hexylresorcinol to a very limited extent. I did not use it according to the dictates of Dr. Leonard. We forced fluids as usual, and I feel that that had something to do with our failure to get results. When I get back I will try hexylresorcinol again. I should like to ask Dr. Leonard how long it is safe to give such a urinary antiseptic.

Dr. Israel Kleiner, New Haven, Conn.: My results with hexylresorcinol were about the same as those reported by Dr. Thomas. In no case did I see a favorable result. In all fairness to Dr. Leonard I want to say that in all the cases fluids were pushed while hexylresorcinol was being given. In our part of the country, the demand for the drug has been so great that the wholesale druggists cannot supply it. The patients taking it now are of necessity only getting it intermittently, although some are stocking up before starting the treatment.

Dr. George Gilbert Smith, Boston: I have used hexylresorcinol in about a dozen cases. Like some of the speakers, I feel that I have not followed instructions accurately, for I have not limited the intake of water. I have given the drug to some patients for two or three months, two capsules, three times a day, but this has not succeeded in clearing up the entire urinary infection. I think Dr. Herman hit the nail on the head when he said that there are very few infections of the urinary tract that are confined to the mucous membrane, and it seems to me that when the infection is beneath the mucous membrane or in the prostate it is asking too much of any antiseptic to expect it thoroughly to sterilize the urinary tract. I think in those cases we must use desquamating doses of silver nitrate, or treat the prostate by massage, and get the infection out in that way. Dr. Leonard has done a great work in getting at the fundamental chemistry of urinary antisepsis, and I feel that on the basis of what he has discovered we are likely to get much better results than we have heretofore.

Dr. O. S. Lowsley, New York: It might be worth while to explain that our bacteriology was all done by the bacteriologic department of the hospital, which is presided over by Dr. William Elser, professor of bacteriology at Cornell University. We place absolute confidence in the results. We have nothing to do with the examination, except to send the specimens. About the complications, we have eliminated them, even to the extent of taking out one bad kidney, and in case a patient has prostatitis, we treat the prostatitis in the usual way. We have also tried to eliminate all foci of infection in the teeth, tonsils and so on, realizing at the same time, and not mixing up the results, that after the elimination of bad teeth and bad tonsils, kidney infection will sometimes clear up by itself. Kidney bleeding will clear up after the elimination of the infection. The drug was recommended by one in whom we had the utmost confidence. Our results have been spectacular. We have tried to follow out his precepts to the letter, without any deviation. We have had patients with gastro-intestinal irritation and have taken those patients off the drug for a week, and then started again and have had no trouble after starting it the second time.

Dr. Leon Herman, Philadelphia: It was far from my intention to question the results of Dr. Lowsley's work; these I accept as evidence that hexylresorcinol will accomplish far more than was claimed for it originally. Dr. Leonard has said repeatedly that this drug is not an "intrarenal" antiseptic; that it has little, if any, effect on deep seated infections of the urinary tract. It would seem from the results reported by Dr. Lowsley that Dr. Leonard was too modest in his claims for the antiseptic value of the drug. I should like to know if his original views have been modified as a result of the report submitted by Dr. Lowsley.

Dr. L. F. Milliken, Philadelphia: This work was by no means exhaustive, and while morphin and atropin combined seem to accelerate kidney function slightly, we do not advise their use as diuretics. We tried to determine in the first series of tests whether these drugs delay kidney function, as many believe that they do. There is one feature in connection with the tests to which I wish to call your attention. There was very little difference in the kidney function in the tests done with morphin and atropin and in those in which these drugs were not employed as determined by the appearance time of the dye and the total percentage eliminated, but according to the index of elimination, the excretion of dye was considerably accelerated after their administration. We did not recover a larger quantity of dye after the use of these drugs, but the kidneys did excrete it more promptly. Answering Dr. Lowsley's question about the kidneys catching up in their function: Ether inhibition of dye excretion is evident only when the animal is kept well under the anesthetic. If it is allowed to come out to the point of struggling, the dye almost immediately appears in the urine. In one case the dye appeared in twenty minutes during the first test. The anesthetic was neglected in this case, and when the dog began to struggle feebly the dye immediately appeared. No dye is excreted as long as the anesthetic is continued. In one hospital case, the anesthetic was continued for more than one hour after the dye was injected, and no dye appeared in the urine until eight minutes after the ether was withdrawn. In the dogs, function, as determined by the appearance time of the dye in the urine, was restored anywhere from six to twenty-two minutes after the ether was stopped. We had learned in some previous experiments that denervation of the kidneys prevented ether inhibition of function, and we began the second series of experiments to determine whether any drug would give similar results. We believe that we have in morphin and atropin drugs that do this.

Dr. Veader Leonard, Baltimore: Recently Dr. Chute emphasized the point that it is better to have a live patient than one with a sterile urinary tract, and that water and lots of it is frequently a prime necessity. It is better to postpone the use of hexylresorcinol or any active antiseptic therapy until the necessity of forcing water no longer exists. Gastric irritation will seldom be experienced if hexylresorcinol is taken only immediately after meals. Rarely will a patient be found who cannot tolerate it. I have not personally observed hematuria. The drug has now been given to thousands of patients, and I am not prepared to admit that it was responsible in the two cases mentioned. Cause and effect have not been proved. Hematuria has not occurred in hundreds of observations on animals and normal men. Until very recently it seemed that hexylresorcinol would never be more than a laboratory curiosity because of its expense. It is bound to be expensive, at least until a new synthesis is devised which employs cheaper materials. Unfortunately, my limited supply has not been sufficient to meet the demands made on it. Hexylresorcinol is not contraindicated in pyelonephritis. We cannot expect prompt disinfection if the renal parenchyma is extensively involved, but in my experience these cases rarely fail to derive some benefit if treatment is persistent. Again, hexylresorcinol is not contraindicated in prostatitis, but no urinary antiseptic could possibly be expected to influence infection so located as to preclude intimate contact with the urine. Except in cases in which infection is confined to the mucosal surfaces, those who expect spectacular results without due regard to proper drainage and foci of infection will be disappointed. Not only must the drug be given in sufficient dosage and with avoidance of large quantities of fluid, but each case must receive the benefit of suitable treatment based on accurate urologic diagnosis.

PELLAGRA ASSOCIATED WITH ANNULAR CARCINOMA OF THE TERMINAL PORTION OF THE ILEUM *

FRANKLIN R. NUZUM, M.D.
SANTA BARBARA, CALIF.

W. L. Bender has recently recorded three instances of carcinoma of the stomach associated with pellagra.[1] He could find in the literature only two similar reports. One, by Rolph,[2] recorded a woman with a skin eruption, glossitis, pharyngitis and mental symptoms considered typical of pellagra, coming on four months before death. At death, a carcinoma of the stomach was found. The carcinoma was located in the cardia and mechanically interfered with the passage of food into the stomach. The second, by Bryan,[3] concerned a patient with symptoms of peptic ulcer for twenty years who developed a dermatitis and stomatitis typical of pellagra. This patient had a carcinoma of the stomach, which was resected, and in two months the skin lesions had completely disappeared.

Three instances of acute pellagra following operations for suspected gastric ulcer are cited by Graves.[4]

Bender reports three instances. In one, a patient with a benign ulcer of the stomach developed pellagra during the period of jejunal feeding. The pellagra disappeared after the patient was placed on a general diet following gastro-enterostomy. The second patient had pellagra secondary to carcinoma of the stomach with pyloric obstruction. Some improvement followed gastro-enterostomy, but the patient died later. The third patient had pellagra associated with carcinoma of the stomach. Death followed operation in this instance. In each of these three instances, pellagra developed after the stomach lesion had caused obstruction to the passage of food.

[4] Graves, M. L., in discussion on Roberts, S. R.: Types and Treatment of Pellagra, J. A. M. A. **75**: 21 (July 3) 1920.

I have observed two instances which are closely related to this subject. In each patient, well defined skin lesions were present, and a diagnosis of pellagra had been made by dermatologists. At death in each instance an annular carcinoma of the terminal portion of the ileum was found.

Case 1.—*History.*—H. S., a white American, aged 58, entered the Santa Barbara Cottage Hospital in the service of Dr. H. O. Koefod, Sept. 7, 1922, complaining of weakness, anorexia, and of an eruption on his hands. He had had typhoid and pneumonia at 13 years of age, malaria at 48, and influenza at 53. He had lived in California all his life.

The present illness started seven months before admission to the hospital, when his nose began to bleed and small pimples were noted to form on the inside. Fainting spells began at this time, especially after exertion, together with shortness of breath, some cough and an expectoration which at times was bloody. Four months previous to admission, the patient noticed an eruption on the back of both hands. The appetite remained good until three weeks before admission. The bowels had been costive for many months and had required a daily dose of magnesium sulphate to obtain a movement.

Examination revealed a sharply demarcated dark red eruption on the back of each hand. Scattered over this area were thin, whitish scales. A similar eruption was found in a sharply demarcated area over the sacrum. On the anterior surface of each leg, there was a pigmented eruption similar in color to that on the hands. General nutrition was poor. The abdomen was distended. Purpuric spots appeared over both lower extremities. The patient was unable to eat, weakness increased rapidly, and he died twelve days after admission.

The laboratory data included a negative blood Wassermann test. Albumin and casts were present in the urine. Blood examination showed: hemoglobin, 30 per cent.; red blood cells, 2,000,000; white cells, 10,700; color index, 0.75; small lymphocytes, 30 per cent.; large lymphocytes, 7 per cent.; transitional cells, 2 per cent.; polymorphonuclear leukocytes, 59 per cent.; basophils, 2 per cent. The stools were repeatedly positive for chemical blood.

Necropsy.—There was a definite hard mass in the region of the ileocecal valve. There was a marked dilatation of the terminal portion of the ileum with a marked retention of fecal matter. The mass in this region was an annular carcinoma appearing in the last 10 cm. of the ileum and not involving the cecum Metastatses were present in the left lung, the hilum of the left lung, the liver and the spleen. The patient died of terminal bilateral bronchopneumonia. On section, the tumor of the bowel was found to be an adenocarcinoma.

Case 2.—*History.*—A German, aged 68, whose family history was negative, had had measles, typhoid and malaria as a young man. He had had gonorrhea on three different occasions. He had been a laborer in mines for many years, but during the latter part of his life had been a tramp.

He entered the Santa Barbara General Hospital, May 1, 1923. He complained of a diarrhea of two months' duration, marked and rapid loss of weight, burning in the bowels, swollen tongue, cough, thirst, weakness and an eruption on the backs of both hands. This eruption had been present for two months.

The urine was normal. Blood examination revealed: hemoglobin, 90 per cent.; white blood cells, 4,200, of which 65 per cent. were polymorphonuclear leukocytes; small lymphocytes, 19 per cent.; large lymphocytes, 8 per cent.; transitionals, 1 per cent. The stools gave a positive chemical test for blood. The temperature was normal up to the last two days of the patient's illness. Death occurred seventeen days after admission.

The patient was emaciated and irrational. The mucous membrane of the mouth was red and edematous, and small ulcers were present. The tongue was swollen. The abdomen was distended. No masses or points of tenderness were found. Involving the back of each hand was a sharply demarcated area of dermatitis. The skin in the involved area was thickened and dull red. In the centers of these erythematous areas, desquamation was occurring. The scales were white and small.

Necropsy.—A tumor was found in the terminal portion of the ileum. There was marked distention of the bowel proximal to the tumor. The tumor was found to be an annular carcinoma involving the last 6 cm. of the ileum, but not extending into the cecum. Section revealed this tumor to be an adenocarcinoma. No metastases were found.

COMMENT

The occurrence of lesions characteristic of pellagra associated with carcinoma of the small bowel has not been recorded, so far as I can determine. The suggestion of Bender that the disturbance of nutrition as a result of the mechanical obstruction caused by the carcinoma seems applicable to these two instances. The etiology of pellagra is still in doubt, one view contending that it is infectious and the other that it is a dietary deficiency lying in the protein content of the diet, as advocated by Goldberger.[5] Experimental data and results of treatment of pellagra patients make the dietetic theory the most plausible. These added instances of disturbance in nutrition as the result of mechanical obstruction of the small bowel give added weight to the dietetic origin of this disease.

Third Avenue and Bath Street.

OBSTETRIC PARALYSIS

REPORT OF ELEVEN HUNDRED CASES *

JAMES WARREN SEVER, M.D.
BOSTON

The careful observation and stewardship of any large number of cases implies a certain responsibility to one's fellow workers. A report should be made of this stewardship so that they may profit by such an experience. I am therefore presenting a brief report of 1,100 cases of obstetric paralysis, in a large number of which I have been able to obtain fairly accurate data. These data will be presented because, by its numbers alone, it is the largest series of such cases ever recorded, and so far as that fact goes, must have a certain fundamental statistical value in establishing facts about this condition of obstetric paralysis.

The accompanying table shows in detail certain data in regard to these cases.

These figures alone, however, will not give one a complete picture of obstetric paralysis, as they record only the conditions occurring at birth, and serve only to suggest etiologic factors.

An analysis of the figures may be of interest. In the first place, there is no reason to expect any difference in regard to the sex.

The right arm was affected 670 times and the left, 430, or about 64 per cent. in favor of the right arm. This is about the usual percentage in other series reported.

---

[5] Goldberger, Joseph: The Relation of Diet to Pellagra, J. A. M. A. 78: 167 (June 3) 1922.

* From the neurologic and orthopedic clinics of the Children's Hospital.

* Read before the Section on Orthopedic Surgery at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

The types of paralysis differed, the most usual one being the so-called upper arm type, of which 829 cases were recorded, as against the so-called lower arm or, a better name, the whole arm type, in which besides the fifth and sixth cervical roots being injured, the seventh and eighth and first dorsal roots were injured. Of this type, 208 cases were recorded. In sixty-three cases both arms were affected, the whole arm type being the least common. It is generally acknowledged that a difficult and prolonged labor is a predisposing factor of the greatest importance in the causation of this type of paralysis. In this series, 584 cases were definitely recorded as long and difficult. In a large proportion of these cases, forceps were used, either high or low; most of the mothers had ether, which presupposes a relaxed and asphyxiated child. All these factors contribute toward establishing the ideal conditions for the production of such a paralysis.

All the conditions noted imply the application of force combined with great muscular relaxation of the child, conditions peculiarly favorable for the production of such an injury. A moderate number apparently had normal labor; that is, no forceps were used and no undue force was exerted. Others reported that the head was delivered naturally, but the shoulder stuck behind the pubes and at that time force was applied.

Obstetric Paralysis in Eleven Hundred Cases

Boys	551
Girls	549
Right arm affected	670
Left arm affected	430
Both arms affected, upper arm type	35
Both arms affected, whole arm type	22
Both arms affected, type not recorded	6
Upper arm type	829
Whole arm type	208
Difficult labor	584
Ether used	502
Normal labor	57
Head presentation, including face	443
Breech presentation, including foot and version	142
Presentation not known	458

In regard to the presentation, we have recorded 443 head or face presentations and 142 breech. The latter class includes versions and footlings. In 458 cases, the presentation could not be determined, but a large majority of these were undoubtedly vertex. The latter figures on the presentation are of interest as showing the much greater frequency of vertex presentations in relation to both types of paralysis. It has been supposed that breech presentations were the usual cause of the whole arm type of paralysis, but these figures refute such a theory. Also, it has been stated that paralysis occurred equally in head or breech presentations; but this is not so. Head presentations combined with a stuck shoulder, and the application of force at that time, resulting in a forcible separation of the head and shoulder, will injure the plexus to any degree, thus producing an upper or whole arm type of paralysis. There is, of course, an undue predominance of primiparas in this series. It must be granted that first babies make a harder entrance into this world than those that follow, and the paralytic conditions seem to exist more with them than with the later children, although these are not by any means exempt. There have been a noticeable number of babies that apparently showed a simple upper or whole arm paralysis at first, but a more careful examination showed various associated conditions due to cord injury. These cord injuries practically always follow breech extraction and are caused by traction and lateral flexion of the trunk They show conditions from paralysis of both arms, partial or complete, due to injury to the plexus, to section of the cord and paraplegia below the point of injury. Many patients show a moderate degree of spasticity of the legs with adductor spasm suggesting a cortical lesion as well. They are of sufficient frequency not to be overlooked.

PATHOLOGY

There are generally two well recognized types of paralysis seen. The more common, the upper arm type, consists of a lesion that involves the fifth and sixth cervical roots and the suprascapular nerve and produces a paralysis of the muscles of the upper arm only, with the exception of the supinators. The less usual type, the so-called lower arm, or whole arm type, is the result of injury not only to the fifth and sixth cervical roots, but to the seventh and eighth, and possibly the first thoracic as well. Here the whole arm is flaccid; there is a wrist-drop and paralysis of the small muscles of the hand There occasionally occurs the pure lower arm type of paralysis without any involvement of the upper cords of the plexus, the so-called Klumpke's paralysis. These cases show a paralysis, usually the result of stretching of the plexus from overextension of the arm in cases of face presentation, and due to injury to the lower cords of the plexus; namely, the seventh and eighth cervical and first dorsal roots. They may at times be bilateral. It is in this type that one often sees inequality of the pupils, owing to the fact that the sympathetic fibers from the deep cervical ganglionic plexus enter the spinal cord through the first dorsal and, at times, through the eighth cervical roots. Injury, therefore, to these roots leads to an unopposed action of the motor occuli nerve.

Pathologically, in the milder cases, the stretching or tearing forces result in a greater or less degree of hemorrhage or edema into the nerve sheaths In others, there may be a rupture of the perineural sheath, accompanied by hemorrhage into the substance of the nerve trunk, associated with a tearing apart or separation of the nerve fibers The latter condition leads, of course, to permanently impaired function and to the formation of scar tissue in the nerve track. In the more severe cases of the upper arm type, there is a partial or complete division of the fifth and sixth cervical roots, which leads to a more permanent form of paralysis than usual, and the formation of a more extensive area of scar tissue.

The force producing these lesions is variable, and so the lesions are variable. The nerve roots are often frayed out inside the sheath instead of being torn across evenly, and in this way the lesion may be incomplete at any given cross section of a nerve, but involves different fibers at different levels This scar tissue contracts in time, and not only effectually prevents the regeneration of the nerves, but, by its contraction, may press on and destroy the few fibers that may have escaped the original injury

The other type, known as the lower arm or whole arm type, is the result of either a lesion involving all the nerves of the plexus, or, in the distinctly lower arm type in which the lower arm and hand alone are involved, of the so-called Klumpke's paralysis, in which the lesion probably involves the eighth cervical and first dorsal roots alone. This type generally results from traction applied in a breech case with the arm extended, or to traction in the axilla in a vertex presentation. Pathologically, the conditions are similto those seen in the other types, depending on the severity of the injury. No case in which operation has been performed has failed to show a definite pathologic lesion of the brachial plexus, definitely corresponding to the muscles involved.

ROENTGEN-RAY FINDINGS

A great number of these patients have been roentgenographed at all ages; that is, the ages of the patients varied from 2 days to 18 or 20 years. The findings have been rather characteristic. In the early stages there has been practically nothing shown in the roentgenogram except an occasional fracture, either of the clavicle or of the humerus. We have been unable to demonstrate any epiphyseal separations or dislocations. As time goes on, the roentgenograms show rather characteristic changes; that is, the shaft of the humerus is a little smaller and the epiphyseal head of the humerus is a little smaller than the one on the well side. The glenoid fossa becomes flattened, particularly in the older babies, when there is a posterior subluxation. In these older babies, associated with the posterior subluxation, there is seen a hooking of the acromion, more or less marked and depending somewhat in its extent on the degree of subluxation.

There is also seen a marked elongation of the coracoid process, due probably to the pull of the contracted coracobrachialis muscle. The scapula is always seen rotated to a certain extent towards the axilla, as well as elevated so that the superior vertebral angle is presented frequently well above the line of the clavicle. One must be on one's guard in certain of these cases to differentiate the condition from Sprengle's deformity or a congenital elevation of the scapula. In regard to the elbow, the roentgenographic findings are of interest. In certain cases, which so far we cannot classify correctly, there appears a subluxation or dislocation of the head of the radius, which extends in some instances well up in front of the lower end of the humerus, and not only blocks flexion but limits supination and pronation.

CLINICAL FINDINGS

Clinically, there is nothing new of any particular importance in regard to these cases. They present practically the usual conditions and run fairly true to type. We have, however, not been sticking quite as closely to our hard and fast line of upper arm and whole arm classification, although this is a fair method, but we find that many cases show certain clinical symptoms of the two types. A certain proportion of young babies are presented to the clinic with what apparently is only the upper arm type of paralysis, but there is also a wrist drop present which ordinarily we have associated with the whole arm type. We have learned to discriminate about this wrist drop in that we are not willing to make any definite statement in regard to the prognosis for at least six or eight weeks, for we find that many of the wrist drops will wholly clear up by the end of that time, and leave nothing but a simple upper arm type of paralysis. When the wrist drop has not cleared up by the end of six or eight weeks, we then classify the type as whole arm paralysis and treat it on that basis.

As I have stated before, the pupillary inequality is of the greatest importance. A good many cases present at first pupillary inequality, with the small pupil on the affected side. If this pupillary inequality persists in connection with the wrist drop, or the whole arm type of paralysis, beyond six or eight weeks, we are sure we are dealing with a serious injury to the plexus, which has probably resulted in an evulsion of the two lower roots of the plexus from the spinal cord, and so breaks the reflex sympathetic arc, which connects with the motor control of the eye. This is an important pathognomonic point, and if the pupillary inequality persists, one may be absolutely sure and safe in giving a bad prognosis.

TREATMENT

The treatment of these cases has not varied very much from that which has been previously described. We are not as insistent on the use of splints from the very start as we were at first, and the reason for the change is this: We have found that in certain cases the use of a splint seems to cause a certain amount of swelling about the wrist and elbow, and makes the exercise treatment, when the splint is removed, painful and difficult. Just why this should occur we have not been able to determine, but it has occurred and makes us a little more guarded in the use of the splint. We have found also that the use of the splint in certain children leads to a slower convalescence and a less free use of the arm, even with adequate treatment, so that we discard the splint, even in the face of the possibility of increasing muscle contractures, because we feel that we may be able adequately to supervise treatment to control the contractures, and in this way give the child a freer and better use of the arm than it would have with the constant wearing of the splint. Operations designed to relieve muscle contracture we undertake freely, as a rule, not earlier than four or five years, and by division of the contracted muscles we find that we are able to give the child a very much better arm, not only from a cosmetic but also from a functional point of view.

In regard to operations on the brachial plexus, we are not taking quite the radical stand that we have taken in the past. We are more willing to operate in certain cases, particularly in those of the upper arm type in which one or two muscles seem to be permanently paralyzed or weakened, so much so that they cannot function successfully. In the whole arm type of cases, when there is no functional improvement at all from muscle reeducation, operation on the plexus is indicated but nothing is promised.

In the whole arm types, we feel that three months is a fair period to try massage and muscle reeducation and if there is no evidence of any functional return during that period, that it is fair at the end of that time to explore the plexus and attempt to repair it.

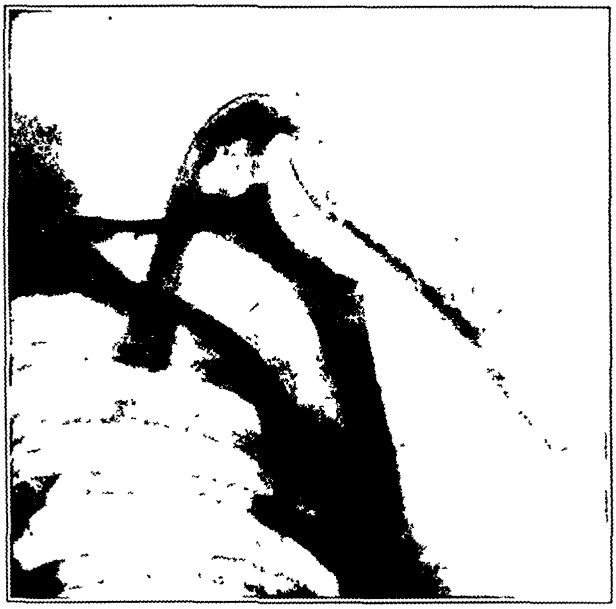
In the upper arm types, we often wait until the children are 4 or 5 years old, because by that time we can also divide muscle contractures that are preventing free use of the arm. We have had no very brilliant results from the plexus repair. Many of the plexuses that have been operated on have shown absolutely nothing in the way of functional recovery, and nothing could be expected from the type of injury found at the time of operation.

A few cases suggest that a plexus operation, always in connection with the muscle operation, may offer a better arm in the end. However, we are not overenthusiastic on this point. In certain of the older children, posterior subluxation of the shoulder joint can be reduced only (1) by means of the muscle cutting operation and (2) by the division and elevation or removal of the hooking of the acromion, which comes down in front of the head of the humerus, and prevents its proper reduction.

In a certain number of cases in which the pronator radii teres has become very much contracted, we have divided this muscle with great benefit.

AUTHOR'S OPERATION

An incision is made on the anterior aspect of the arm, beginning at the tip of the acromion and carried down to below the insertion of the pectoralis major. The cephalic vein is found generally in the outer edge of the wound and tied or retracted outward. The tendinous insertion of the pectoralis major is then defined, raised on an instrument, and divided all the way across. The pectoralis major muscle is then retracted inward, out of the way, bringing into view at the bottom of the wound the inner edge of the coracobrachialis muscle. This muscle is then defined upward until the coracoid process is reached, the arm being outwardly rotated and abducted. The tip of the coracoid process, which is usually found elongated, is completely separated from its base, together with the insertion of the coracobrachialis, the short head of the biceps and the pectoralis minor. Not more than about one fourth or three eighths of the tip needs to be removed to accomplish this. This allows the coracobrachialis and the short head of the biceps to retract downward out of the way, and allows much freer outward rotation and abduction of the arm. The capsule of the shoulder joint is then seen in the bottom of the wound as well as the three horizontal circumflex veins. Just above the upper vein is the lower edge of the subscapularis tendon. This lower edge should be defined. A curved instrument is then inserted just underneath this tendon, which is fairly wide at this point, and the tendon completely divided on the instrument. This prevents any opening of the shoulder joint capsule; and, once this subscapularis tendon has been divided, outward rotation, abduction and elevation of the arm are perfectly free.



Old case of obstetric paralysis, showing deformity of head, marked hooking of the acromion, flattening of the glenoid, and subluxation of head.

The only condition then that will block free outward rotation, abduction and elevation is a considerable degree of hooking of the acromion. If this condition exists, such portions of the acromion as block the restoration of the head of the humerus to the glenoid should be removed. The operation is then complete and the only stitches needed to close the wound are stitches to the fascia and skin. The arm is then put up on a splint in an abducted, elevated, outwardly rotated and supinated position.

Muscle reeducation, active and passive use of the arm, begins just as soon as the stitches are out, which is in about eight or ten days.

We have operated in about sixty or seventy cases. Our results have been satisfactory, that is, in the upper arm types, and while we cannot restore the arms to normal, we can improve them functionally, so that they are very useful.

There are one or two preoperative conditions that have bothered us a good deal: 1. For about a year after this operation, and sometimes even longer, there is considerable difficulty in inwardly rotating the upper arm, or in putting the hand on the opposite shoulder. 2. In almost all cases after operation there is a good deal of limitation of rotation in the joint itself, which, however, is eventually overcome. 3. With the arm hanging at the side, there persists almost always a considerable rotation of the scapula in a vertical plane, even when there is apparently free motion of the shoulder joint. Just why this is we have not been able to determine. It does not impair the function of the arm, but does not make for a cosmetic success.

CONCLUSIONS

In the main, our experience has been that if we can get our babies early, we can in a great many instances prevent later operations, that is, on the upper arm types, and we can give them fairly good functional arms, with the exception of the ability to supinate normally. In old cases in which there has been no treatment, operation has to be performed almost invariably

Children are better treated under the eyes of a physician and a properly trained masseur or nurse. Better results are obtained in this way than with those babies left to the parents' care. We have to leave a great many babies to the parents on account of economical and social conditions, and because they live far from the clinic. We do not like to do so, because our results are never as satisfactory.

The treatment is, as in every condition occurring in babyhood, to be begun immediately and should be carried out faithfully for years, and except in the whole arm type of paralysis, a fairly good functional arm can be hoped for. Arms, when first seen, should never be put in a sling or a Velpeau bandage, but should be either left entirely free with the other arm pinned, or should be put on a splint.

321 Dartmouth Street.

Cost of County Health Department.—For all except the most sparsely populated and poorest counties, the minimum cost of a county health department should be at least $10,000 a year. In the more populous counties, a larger budget will be needed to secure adequate service. In general, it may be stated that an expenditure of 50 cents per capita per annum should furnish a county with reasonably adequate health service. (This does not include hospital expenses, bedside nursing, or pauper relief.) A budget of 25 cents per capita should be the minimum in any except the poorest counties.—Parran, Thomas, Jr.: Cooperative County Health Work, *Pub. Health Rep.* **40**:986 (May 15) 1925.

BIRTH INJURIES REQUIRING ORTHOPEDIC TREATMENTS *

SAMUEL W. BOORSTEIN, M.D.
NEW YORK

In the last few years, proper and immediate treatment of the child for injuries received at parturition has been instituted. The prognosis in these serious injuries has therefore been greatly modified. The profession at large and the lay public recognize that many of the conditions, classified till now as congenital, are really but later manifestations of traumatic lesions sustained at birth. These lesions remained undiagnosed in the new-born, possibly because their symptoms were not recognized, but more probably because the obstetrician failed to examine the new-born with the necessary care. If the infants are properly examined immediately after birth and the early symptoms looked for, a fair diagnosis may perhaps be reached. A great many of the later disabling deformities can be avoided should the obstetrician consult the orthopedic surgeon shortly after parturition. Many of these cases could be entirely cured. It is my purpose in this paper to impress on the profession the necessity of very early orthopedic treatments. The methods should be stressed in the medical schools. Some of these treatments can be instituted by the general practitioner himself.

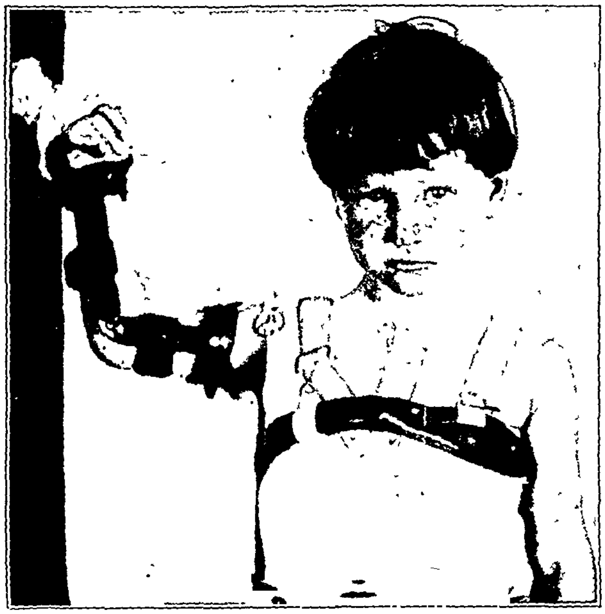


Fig. 1.—Patient with Erb's paralysis after a Sever operation, showing the proper position in which a deltoid brace should be worn in such cases.

GENERAL CONSIDERATIONS

A birth injury refers to traumatic injuries sustained during labor and delivery and in the common and necessary manipulation of the new-born. Ehrenfest[1] arrives at the following conclusions:

> I lay stress on the fact that the child can be more or less severely traumatized also in a normal labor, in a spontaneous labor, if we grant that the term "spontaneous" by common consent includes as well deliveries in which the expulsion of the fetus is actually hastened by a dose of pituitary extract. In by far the larger number of instances, however, serious traumas are observed after labors terminated by operations or other artificial means.

Such statements, coming from so noted an obstetrician, should be a warning to prevent occurrence of birth injuries. If this warning is heeded, no orthopedic care will be necessary.

The best results in all these injuries can be obtained if the treatments are instituted early. The obstetric services of the general and special hospitals should include in their armamentarium the orthopedic appliances to institute early treatment.

INTRACRANIAL INJURIES

Intracranial injuries constitute the most serious and pathetic cases and embody the idiotic, epileptic, Little's, paraplegia, diplegia, hemiplegia and monoplegia. Ehrenfest[2] says:

> For the majority of them, the responsible mechanical cause is recognized in definite anomalies of labor, breech labors, extraction of the aftercoming head after version, difficult forceps extractions, especially in the cases of mechanical dystocia, etc. In spontaneous delivery, the immediate cause of the injury is a mechanical one, the compression of the head on its passage through the birth canal, both through its bony and its soft portions.
>
> In the presence of only slight intracephalic traumatic lesions, a decreased coagulability of the blood and inappropriate manipulations during resuscitation necessarily tend to hasten or to prolong the escape of blood from injured vessels, though small, and thus represent important contributory factors in the causation of cerebral hemorrhages.

The pathologic condition is a lesion of the motor area of the brain. This is followed by atrophy, retarded development, sclerosis or softening of the affected portion and a degeneration of the pyramidal tracts and later the columns of the cord.

Symptomatology.—The symptoms of late cases are well known and need not be repeated here. Effective therapy, often life saving, is plainly dependent on early diagnosis. As most of the deliveries are performed by the general practitioner, it is he who must familiarize himself with the early symptomatology so that he will be able actually to diagnose, or at least to know when to suspect, such injuries.

The early symptoms are as follows: The infants are very restless and cry almost incessantly. Pressure on the fontanel produces respiratory distress, screaming or even convulsions. If the hemorrhage is not excessive, these infants refuse to nurse. Nursing usually is poor and clumsy. Retinal hemorrhages, inequality of the pupils, squinting and nystagmus are often found.

Obstetric prophylaxis is out of the sphere of this paper.

Orthopedic Prophylactic Treatments.—I agree with Steindler[3] when he says:

> In no form of paralysis is the importance of prophylactic measures so great in preventing deformities as it is in spastic paralysis; and in no form of paralysis has it been so little used and the possibilities of prophylaxis so grossly neglected

---

[3] Steindler, Arthur: Reconstructive Surgery of the Upper Extremity, New York, D. Appleton & Co., 1923.

as in this very type. The measures to prevent contractures must be instituted at the earliest possible moment. This is even more urgent in spastic cases than in flaccid paralysis, where the deformities develop more gradually and are, for a longer time, amenable to correction.

The prevention of contractures has been followed by all progressive orthopedists in anterior poliomyelitis, in obstetric paralysis and in peripheral nerve injury. In previous papers I[4] have shown that, in hemiplegias occurring in adults, all the deformities can be prevented if plaster is applied immediately after the apoplectic attack. It seems logical, therefore, that this should be efficacious in these infants. A small Thomas double abduction frame with attachments for the hands to keep the shoulders abducted and rotated outward, and provisions for increasing the abduction of the lower extremities, will do the work well. There must be foot pieces to hold the feet at a right angle. The flexion contracture of the elbow is usually not as rigid as the contracture of the wrist joints. If the angle of flexion is suitable, one need not change it. For the elbow, we may use a Funsten brace advocated by Steindler.[3] For the hand, a Jones cock-up splint is used. If the symptoms point toward hemiplegia, we should use the same methods for one side only and pay special attention to the Achilles tendon and to the wrist. Such splints can be kept at hand like Thomas Jones splints for fractured femurs.

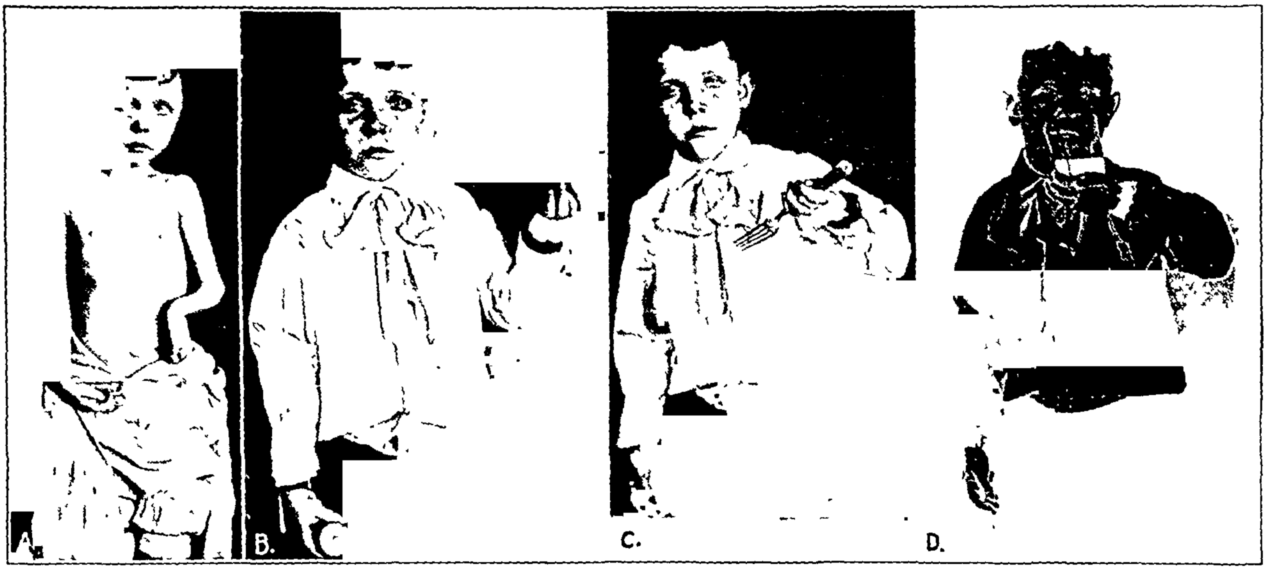

Fig. 2.—Very severe case of double obstetric paralysis, lower arm type: *A*, Nov. 23, 1920, before treatments, showing position of hands and the deformities; *B*, Aug. 23, 1923, after operations, showing ability to throw ball with the right hand; *C*, Aug. 23, 1923, showing ability to use a fork with the left hand; *D*, Aug. 23, 1923, showing ability to drink with the left hand.

The braces can easily be applied and used for a few weeks. Even if no further symptoms develop, it will have been worth while. Massage and similar treatments are instituted when advisable. We cannot predict the mental deficiency, but the deformities prevented will have a beneficial effect. (We know that even in later life the mental condition often improves if the contractions are removed.)

I have had quite a few cases treated in this manner in early infancy with most encouraging results. Unfortunately, none of these cases came to me when only 1 or 2 days old. They are very seldom referred to us so soon. I hope that articles such as this will stimulate the obstetrician to refer them early.

If the child is seen later, the general treatments advocated by the orthopedists are used. Jones and Lovett[5] outline these treatments as follows: muscle reeducation; operations on the muscles or tendons as tenotomy, myotomy and muscle transplantation; operations on the nervous system such as cerebral decompression, Forster's operation, Stoffel's operation, and alcohol infiltration of nerves. At present we add the new method of sympathetic ramisection advocated by Royle.[6]

The treatment of the mental condition of the child is beyond the scope of this paper.

OBSTETRIC BRACHIAL PARALYSIS

Obstetric brachial paralysis, which up to a few years ago was considered incurable, has been brought before the profession by Taylor,[7] Sever,[8] Fairbank,[9] Platt,[10] and myself.[11] The etiology has been cleared up. The condition is now considered curable, and the earlier the treatments are instituted the better are the results. The orthopedic surgeon is now being consulted very early and thus he has a chance to prevent the distressing and disabling deformities and frequently to institute a complete cure. In a previous article,[12] I gave the following conclusions:

1. Obstetric brachial paralysis is due to stretching or tearing of the cervical roots of the brachial plexus.

[12] Boorstein (Footnote 11, second reference).

2. It is almost always associated with a difficult labor; in many instances, forceps having been used.

3. If these cases are treated early and properly, one may expect in the mild cases a good recovery in three or four months.

4 The more severe cases will require about six or seven months for a complete recovery.

5. Nerve operations are indicated if no advance is made in four months. After that period, if sufficient improvement is noticed one may wait four months more, provided, of course, proper orthopedic treatments are continued.

6. The shoulder should immediately be put up in a splint or brace to prevent stretching of the paralyzed muscles and contracture of the unopposed muscles. (Figs. 1 and 8 *B, D.*).

7 Even in the whole or the lower type, one may try conservative treatments for a while and then resort to a plexus operation. The result is not so discouraging as some textbooks would lead us to believe (Fig. 2).

FRACTURES

There are two kinds of fractures: (1) true fractures due to a definite trauma from without, and (2) pseudofractures due to amniotic adhesions, amniotic bands and intra-uterine pressure. Some of the uterine fractures produced at the delivery are really due to a previous existing intra-uterine disease. Whether the disease is responsible for the fracture or the trauma used at the delivery, it is certainly acknowledged that of all the birth injuries this is the most embarrassing. Any one who has been so unfortunate as to hear suddenly the crack of a bone after a hard delivery and has looked around at the family standing near-by will never forget the situation. He is certainly anxious to obtain assistance quickly. He may trust the textbooks which assert that the fractures usually heal, but he must know how to fix them up immediately. For such accidents the student and the general practitioner must be prepared in advance.

The bones most commonly fractured are the femur and humerus. The humerus is broken both in vertex and breech labors by being firmly pressed against the symphysis. This pressure is exaggerated by traction on the fetus. Fractures of the femur are usually transverse in its upper half or third. Fractures of the tibia and fibula are usually produced in the management or mismanagement of breech labors.

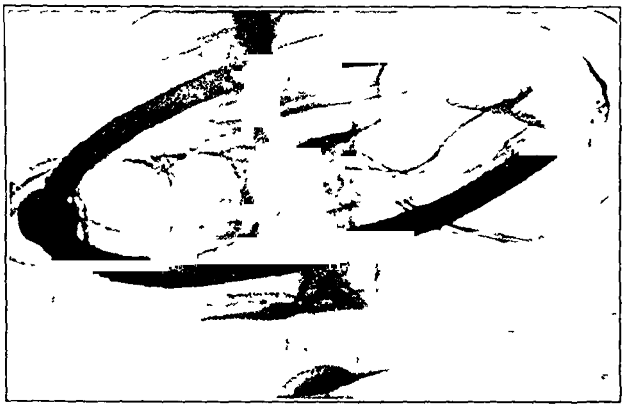

Fig. 3.—Fracture of the femur, showing improper adjustment of the Thomas Jones splint; this was afterward corrected.

Fractures of the Clavicle.—These are more common than formerly believed. They are found in vertex as well as in breech presentations and are usually transverse. The arm lying limply at the side should suggest the possibility of this fracture in addition to brachial palsy. The prognosis is good.

A separation of the epiphysis of the humerus may also be found at the shoulder as a result of traction, but it is hard to recognize unless symptoms are noticeable.

Injuries of the Cranial Bones.—Ordinarily these are mere fissures or deep indentations that do not give rise to any visible anomalies. The dangers are usually the result of intracranial injuries.

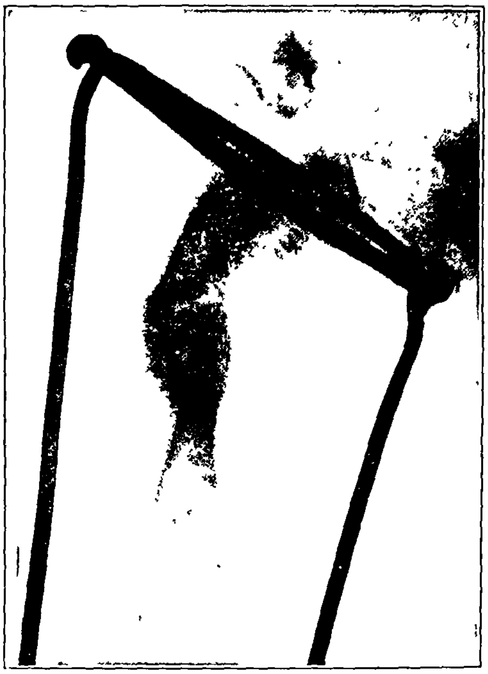

Fig. 4.—Fracture of femur: splint in place, with marked callus present.

Fractures of Vertebral Column.—These are common in version and extraction, often causing an injury to the cord also. Hyperextension of the vertebral column in the Veit-Smellie maneuver makes that procedure dangerous. The symptoms are often those of cord injury. A roentgenogram should be taken of the spine in each case of suspected spinal injury.

Diagnosis.—In diagnosing a fracture to determine whether it was sustained during birth or within the uterus, it might be helpful to note that, according to Jones and Lovett,[5] fractures at birth are healed with some deformity over the apex, and there is generally a dimple or scarlike mark.

Treatment.—Many complicated methods have been advocated for the treatment of fractures of the upper and lower extremities. In a previous paper, I[13] discussed these methods in detail and came to the conclusion that a Thomas Jones splint can be used. A half ring is more adaptable in these cases. The ring must not be too wide, as it will press on the axillary vessels, if the case is one involving the upper extremity, and thus produce a deformity. I have used the Thomas Jones splint in many cases and have become convinced of the ease with which the splint can be applied in fractures of the femur, humerus, tibia, fibula and the forearm bones. I have become impressed by the good results that almost invariably follow the use of the splint (Figs. 3, 4 and 5).

---

[13] Boorstein, S. W.: Treatment of Birth Fractures at Fordham Hospital, Am. J. Dis. Child. **19**: 375-383 (May) 1920.

The advantages are that it allows easier transportation, permits cleansing of the children and saves a great deal of watching. It permits early massage. The deformity is easily controlled. The union probably occurs earlier on account of the ability of the infant to use the limb, to elevate it together with the brace.

In fractures at the elbow joint, acute flexion (the Jones principle) should be followed. This can be done with the plaster of Paris or a flannel bandage.

For fractures of the clavicle—though some suggest that no treatments are necessary—I have always considered some form of treatment advisable. It can be immobilized by a figure-of-eight flannel bandage to the other shoulder, but one should protect the axillae by putting felt under the bandage (Fig. 6).

Treatment of separation of the epiphysis of the humerus should consist of immobilization on a deltoid abduction splint.

For fracture of cranial bones, the symptomless case is best let alone; but if there are signs of an intracephalic disturbance, the treatment should be surgical. It is hard, however, to decide when to operate, and these doubtful cases should be watched very carefully for a few weeks to note symptoms of intracranial pressure. The orthopedic treatments for the extremities should, however, not be neglected. We may hope that the carefully recorded necropsies on the early deaths may help us to decide when to operate.

TORTICOLLIS

Of the other injuries sustained at birth, torticollis should be mentioned. Meyerding[14] supports the congenital theory, but says that it may be due to trauma at or preceding birth. Stern[15] reports a rare case to support the theory that congenital torticollis is due to an abnormal attitude and lack of space in the uterus. Still, many cases of obstetric paralysis or fractured clavicle give evidence of injury of the sternocleidomastoid. Jones and Lovett[5] are of the distinct opinion that hematoma of the sternocleidomastoid often produces torticollis.

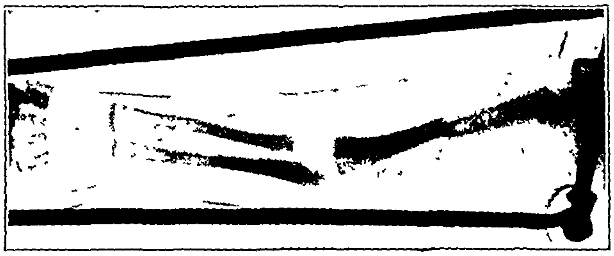

Fig. 5.—Birth fracture of the humerus in a Thomas Jones splint, showing how the fragments can be held with that splint

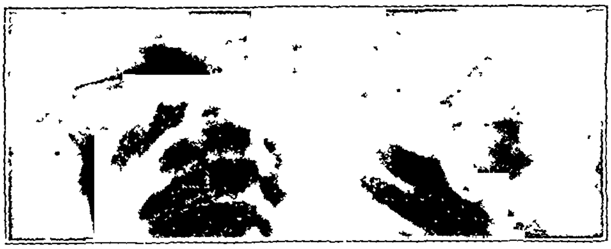

Fig. 6.—Birth fracture of the clavicle: good position and abundance of callus

Treatment.—Support is needed and can easily be given by a felt collar applied to the neck to keep the head straight. One can put soft flannel underneath. The felt collar does not interfere with the nursing and is removed for massage (Fig. 7).

CONCLUSIONS

1. Many permanent injuries are traced to parturitional trauma.

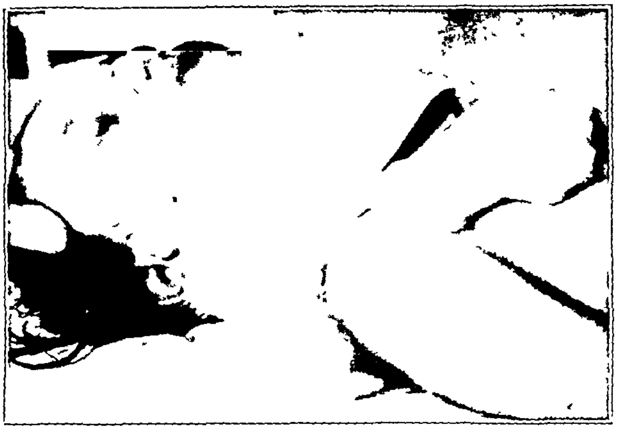

Fig 7.—Application of a felt collar after operation for torticollis; final result with this immobilization was very good; it may be applied immediately after birth without discomfort

2. Many of these injuries can be diagnosed at birth if careful examination is made.
3. The obstetrician or the general practitioner should acquaint himself with the proper methods of prompt diagnosis so that early treatment can be instituted where necessary. If he himself cannot diagnose the case, he should consult the orthopedic surgeon.
4. The spastic cases should be treated at once even when we are in doubt whether the mental condition of the child will ever be normal. One cannot foretell how much mental recovery will be obtained.
5. The armamentarium of the obstetric service in the hospital should include the braces or wire splints necessary for immediate attention in these cases.
6. Cases of intracranial injury are treated by a double Thomas abduction frame with arm attachments.
7. Obstetric brachial paralysis is best treated by a plaster or an abduction splint keeping the arm in abduction and outward rotation. Later on, massage and exercises are instituted.
8. Fractures of the femur and the humerus are treated with a small Thomas Jones splint.
9. Fractures of the spine are treated by means of a Bradford frame.
10. Torticollis is prevented by a felt collar around the neck.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SEVER AND BOORSTEIN

Dr. J. T. Rugh, Philadelphia: There is no doubt that the accuracy of observation of the general run of practitioners is not as keen as it should be The education of the practitioner constitutes a large field of our work: not that we can make orthopedic surgeons out of them—that is an impossibility—but that we draw their attention to the frequency of malformations at the birth of the child, and the necessity of the early recognition of these conditions. There are several points that I wish to emphasize. In the first place, Dr. Boorstein advocated the equipment of our hospitals with orthopedic appliances that will enable the obstetricians or the surgeons to take care of these cases. There are two distinct types of the work presented in both of these papers. One is the work by the general practitioner in the home of the patient, and the other is the work of the obstetrician and the surgeon in institutions. There is a marked difference between them, and I believe that our greatest work lies with the practitioner in the home, rather than in institutions. It is very nice to have an equipment that will enable the practitioner to take care of these deformities when they arise, but how many of them know how to use mechanical appliances? In regard to the special types of deformities, congenital fractures have been mentioned. There is one I would call attention to that has proved most troublesome, and that is the congenital fracture in the lower third of the tibia, often due to a congenital cyst or to some disease condition in the lower end of that bone of unknown origin. Those cases have proved in my hands the most troublesome type of congenital fractures, and in several instances have ultimately resulted in amputation of the leg. I want to stress the importance of the classification of the obstetric paralyses of the arm as given by Dr. Sever. We must make more accurate observations as to the type of paralysis, whether the upper arm type, the lower arm type, or the total paralysis. The other point I wish to mention is with regard to cases of congenital torticollis. I feel very strongly that there is in the majority of these cases a traumatic element rather than a congenital condition.

---

[15] Stern, A.: Etiology of Congenital Torticollis, Monatschr. f. Geburtsh u. Gynak. 65:179, 1924.

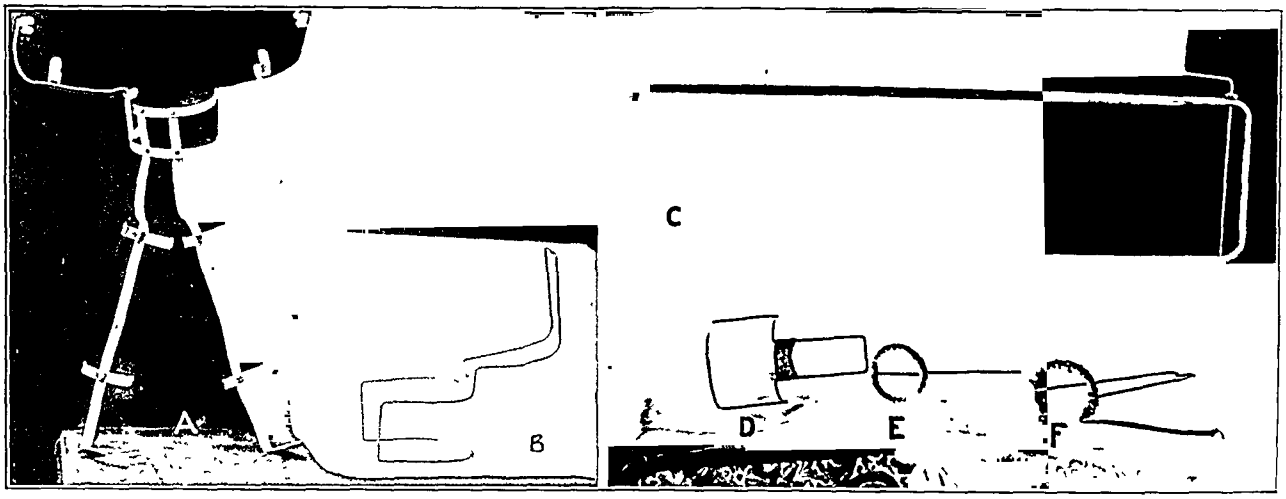

Fig. 8.—Armamentarium of orthopedic appliances for obstetric service: *A*, Thomas abduction frame; *B*, wire splint for obstetric paralysis; *C*, Bradford frame, with a windlass; *D*, wire splint for obstetric paralysis, with a narrow body frame; *E*, small Thomas Jones splint with a closed ring; *F*, small Thomas Jones splint with half ring.

Dr. H. J. Fitzsimmons, Boston: One of the authors and Dr. Rugh have somewhat misled us in stating that the congenital torticollis is correctible by a simple apparatus. A congenital torticollis is one in which there is a congenital shortening of the muscle. The ones that Dr. Rugh mentioned are acquired. They may be due to obstetric injuries, but the majority of congenital torticollis cases are not. This is an observation made from a study of more than 500 cases. They are found in extra-uterine pregnancies and in conditions in which there has been no trauma, and certain of the hematomas that are found after strenuous deliveries and injuries are not followed by torticollis.

Dr. G. I. Bauman, Cleveland: I have been impressed with the fact that injuries to the sternocleidomastoid are not at all uncommon. To my knowledge, none of those cases have been followed by a torticollis. The sternomastoid muscle is changed from ordinary muscle tissue to fibrous tissue. In other words, there is a fibrosis of the muscle, and that is not usually the result of a trauma in other muscles. I should like to ask Dr. Boorstein whether he has seen a real torticollis following a hematoma in the sternomastoid muscle. A few years ago I examined a baby with a double obstetric paralysis, absolutely symmetrical, and of the whole arm type. Has Dr. Sever seen any similar case?

Dr. Samuel W. Boorstein, New York: Dr. Rugh mentioned that there is a great deal of difference between treating these patients at home and in institutions. Of course, orthopedic surgeons can treat these cases better, but I did not want to appear too self-interested by making the statement that all cases should be sent to them. Besides, as Dr. Sever said, many of these patients live out of town, and the general practitioners should know how to take care of them partially, and see the orthopedic surgeon occasionally. Dr. Rugh mentioned congenital torticollis, and Dr. Bauman asked me whether I have ever seen a case following hematoma. I have not. I said that in many cases that does follow and that Jones and Lovett gave it as a cause that it may very often follow, and I felt it was worth while to prevent its occurrence.

Dr. J. W. Sever, Boston: It is poor obstetrics in many instances that gives us these serious conditions. The thing to look for is an arm that lies at the side perfectly weak and paralyzed, inwardly rotated, the hand pronated, and no muscle power whatever, unequal pupils, frequently ptosis of the eyelids, sometimes a facial paralysis. That is a perfectly typical, complete picture. When one has a case like that, one should not tell the parents that the child is going to make a perfect recovery. I have never seen a perfect, complete recovery under any conditions. These patients always carry through life a picture of obstetric paralysis of the arm. I did not suppose that the question of hematoma ever entered into the question of torticollis. I have never seen a case of torticollis following hematoma. I supposed the theory had been accepted as shown by Josserand and Viannay in 1906 that it was due to an intra-uterine position in most cases which held the head in such a position that the arterial supply from the superior thyroid artery to the sternomastoid muscle was cut off, and as a result there occurred a contraction or fibrosis of the sternomastoid. That is apparently the accepted and true cause, at least as far as we know, of congenital torticollis. In regard to the double arm type of obstetric paralysis, we have had a number of cases which I have reported. They rarely are symmetrical. One arm usually is a little bit better than the other; one gets a little bit better as time goes on. I have never seen an absolutely symmetrical double arm type.

KIDNEY STONE AS A DIAGNOSTIC PROBLEM *

B. H. NICHOLS, M.D.
CLEVELAND

No consideration of kidney stones as a diagnostic problem is complete without a review of the clinical and urologic symptoms presented by this type of disease of the kidney. If we are to study only the cases in which the suspicion that a stone may be present is aroused by pain of the renal colic type, then many cases of renal calculus will remain undiagnosed. There are many cases in which pain in the genito-urinary tract is a minor complaint or is entirely absent, and I feel that in such cases, which present an atypical symptomatologic syndrome, the liability of an error in diagnosis is most apt to occur. In order to obviate this, a wholesome respect must be paid to all the symptoms that may be present in a patient suffering with a calculus of the kidney.

I am prompted to prepare this paper by the frequency with which kidney stones are found by roentgen-ray examination in patients who have been referred to me for the roentgenologic study of structures other than the kidney. In consequence, I have come to believe that in many cases kidney stones are not apprehended on account of insufficient or atypical symptoms. In order to arrive at a conclusion regarding the significance of certain clinical symptoms of calculus of the kidney, I have analyzed a series of cases to determine the frequency of occurrence of certain symptoms, together with their characteristics, and will consider them in the order of the frequency of their occurrence in this series.

SYMPTOMS

As is shown in Table 2, pain is the most constant symptom of kidney stone, having been present in 86 per cent. of the series. It is of two types: (1) aching or continuous pain, and (2) colicky pain, the so-called renal colic.

There may be a history of long standing pain with alternating periods of relief and exacerbations. When pain is accompanied by pyuria, hematuria or frequency it is reasonable to suspect that it is due to a renal calculus, and a roentgen-ray study of the kidney should be made.

Renal colic usually has a sudden onset and may require the use of an opiate for relief. If the colic is accompanied by microscopic blood or pus, the presence of calcium oxalate in the urine or uric acid crystals, together with a history of previous attacks or of the previous passage of gravel, then a roentgen-ray examination of the kidney should be made, with the expectation that a kidney stone will be found.

Next to pain, pyuria is the most common symptom and was present in 77 per cent. of this series. The presence of pus in the urine, particularly in the absence of an infection of the bladder or urethra, should always suggest the possibility of a kidney stone, especially if there is pain in the region of the kidney.

Hematuria was found in 44 per cent. of the cases. When accompanied by pyuria and pain, this is a suspicious symptom and a search should be made for kidney stone.

---

* Read before the meeting on radiology in the Section on Miscellaneous Topics at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

The symptoms of lesser importance, unless accompanied by pain, pyuria or hematuria, in the order of their occurrence in this series, are: frequency, 30 per cent.; nausea and vomiting, 26.5 per cent.; fever, 14 per cent.; chills, 9.17 per cent.

Other points of more or less importance that have been brought out in the study of this series have been the markedly higher incidence in males (63.4 per cent.); the association of the stone with hydronephrosis in 25 per cent. of the cases; the recurrence of stones and a history of a previous operation for stone.

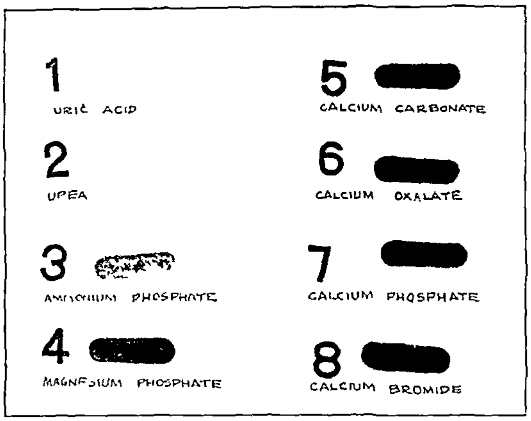

Fig 1.—Roentgenograms of capsules filled with various salts found in kidney calculi

To determine the radiability of the various types of kidney calculi, I have determined the radiability of the usual salts found in calculi by taking roentgenograms of ordinary capsules which had been filled with the pure salts (Fig 1). These studies show that uric acid has the least, and calcium bromid the greatest density; the order of density of the other salts is: uric acid, urea, ammonium phosphate, magnesium phosphate, calcium carbonate, calcium oxalate, calcium phosphate and calcium bromid.

Cystin and xanthin, both of which are rare salts, were not studied.

TYPES OF KIDNEY STONES

Kidney stones are of two types: primary, or essential, and secondary. Stones of the essential type are formed without any apparent primary disease. This may not actually be the case, however, as it is probable that a primary disease has existed but has caused no recognizable symptoms. The formation of these stones is undoubtedly due to a sedimentation of the urinary salts, while the secondary cases are always formed about a nucleus of pus or mucus as the primary factor.

The principal chemical salts that are found in kidney calculi are uric acid, urea, calcium salts, particularly calcium oxalate, phosphates and cystin and xanthin. These salts may be pure or may be present in various combinations. The vast majority of calculi, especially the primary stones, are formed from uric acid and are often found in acid urine, associated with uric acid and crystals of urea. Uric acid stones are reddish brown, with a tendency to yellow tint. They are usually small and multiple, rather hard and faceted. They may be found as the nucleus of larger stones surrounded by a phosphate or oxalate deposit. If small, however, they may often be missed, especially if they are of a pure uric acid formation.

Fortunately for the roentgenologist, most calculi that have been present for some time in the kidney have incorporated phosphate or calcium oxalate in their formation, the high density of which is of material aid in their recognition. On the roentgen-ray film these stones show a density far beyond that of the surrounding kidney tissues; they are irregular in outline and, as previously stated, are usually multiple.

Stones formed from calcium oxalate are of a dark brownish, are rather regular in outline and have a rough surface, giving the so-called nutmeg appearance. Oxalate crystals are usually found in urine that is acid in reaction. These stones give a very distinct shadow on the roentgen-ray film and, as they are a secondary formation, they are usually large.

Calcium phosphate stones are formed rapidly and are irregular in outline. The urine in these cases is filled with phosphatic deposits and is alkaline in reaction. These stones are of medium density and are usually shown on the film. Cystin and xanthin stones are extremely rare.

With modern methods of examination, a large majority of kidney stones may be apprehended as suspicious shadows, on the primary examination. In all cases both kidneys should be examined, to rule out the possibility of bilateral calculi.

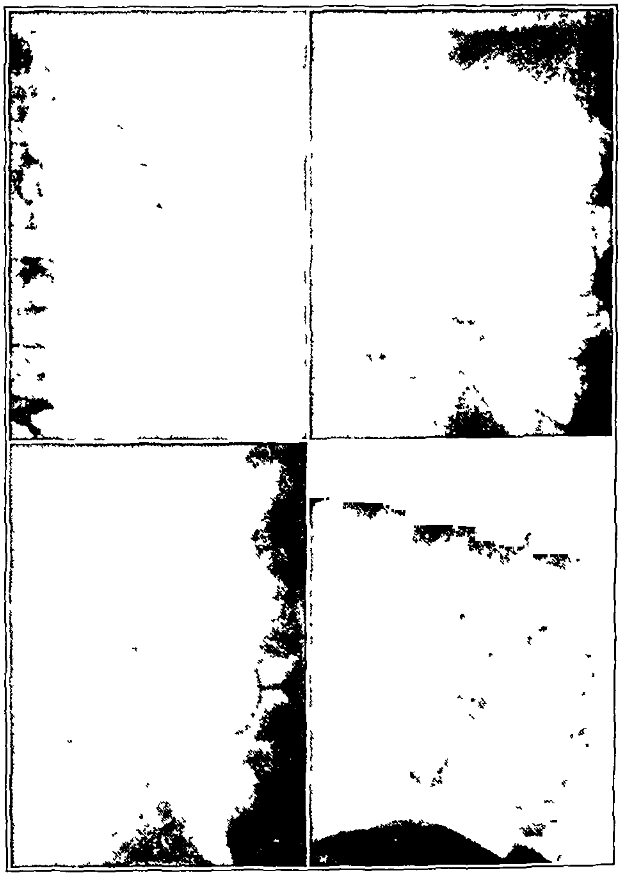

Fig 2.—Appearance of different types of calcified glands on the roentgen ray film

Shadows outside the kidney that may be confused with kidney calculi are gallstones, calcified glands (Fig. 2) retroperitoneal and mesenteric enteroliths, dense bone in the tip of a lateral vertebral process, foreign bodies in the soft tissues, especially in the intestinal tract, calcified venous aneurysms, warts on the skin, postoperative scar tissue, stones in the upper ureter, defects in the film and broncholiths. Shadows within the kidney simulating stones are usually tuberculous calcifications. In a great majority of cases, stereoscopic films will rule out the extranephritic shadows. Calcified glands have a characteristic irregular appearance simulating calcifications in soft tissue. Repeated examinations will rule out gastro-intestinal shadows. The patient should be inspected at the time of examination for warts or any other condition on the surface of the body, such as postoperative scars, which may cast a shadow; in case of doubt, two films will eliminate the artefact. Ureteral calculi will be apprehended by catheterization of the ureters and a ureterogram. Plain kidney films or a pyelogram may show whether or not the shadow is within or outside the kidney.

Tuberculous calcifications are characterized by multiple irregular and widely separated shadows within the kidney outline. Confirmation of this indication may often be established by the characteristic signs of tuberculosis, as shown by the pyelogram or by the presence of pus in the urine.

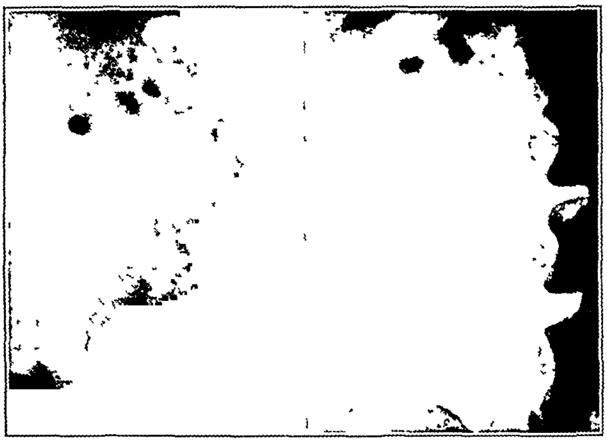

Fig 3.—Posterior anterior and anterior posterior views of kidney stones.

Of especial importance is the differentiation between gallstones and kidney stones. In some cases this may be established by the general appearance of the shadows. Gallstones usually produce more or less clearly circumscribed shadows. Many of them have an outer layer rich in calcium salts, which gives a ringlike shadow with a more translucent center. Gallstones are more often multiple than are kidney stones, their arrangement corresponding to the shape and location of the gallbladder.

Kidney stones, on the other hand, are usually irregular in shape, their form often corresponding to that of the kidney pelvis or calices; or, in some instances, the stone may fill the pelvis and have branches that extend into the calices. The shadows of kidney calculi are almost always of a homogeneous density, which is quite unlike the typical gallstone shadow.

In a fairly large percentage of cases, however, calculi cannot be identified by the size, shape or general appearance of their shadows, and in such cases specific means of differential diagnosis are required. The method that I have found of the greatest value is the use of the anterior-posterior and the posterior-anterior exposures in accordance with the principle used in the localization of foreign bodies. The greater the distance of the foreign body from the film, the greater will be the size of the impression on the film (Figs. 3 and 4).

In general, we may say that when the shadow of a stone on the posterior-anterior or gallbladder film is smaller, more distinct in outline, lower in position and nearer the vertebral column than the shadow of the same stone in the anterior-posterior or kidney film, the diagnosis of a gallstone may safely be made (Fig. 5).

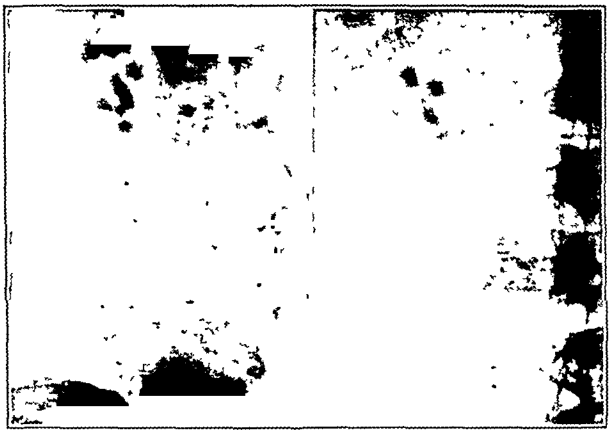

Fig 4.—Posterior-anterior and anterior-posterior views of kidney stones.

I have found that the most valuable auxiliary measure is a pyelogram, which in the case of a kidney calculus will locate the shadow in the pelvis of the kidney (Figs. 6, 7 and 8). In the case of a gallstone, the shadow on the pyelogram will almost always lie outside the kidney pelvis. If it also lies outside the kidney in either the gallbladder film or the kidney film a calculus in the pole of the kidney will be ruled out, as a stone in this location must of necessity be associated with the kidney shadow in all exposures. It should always be borne in mind, however, that a patient may have both gallstones and a right kidney calculus.

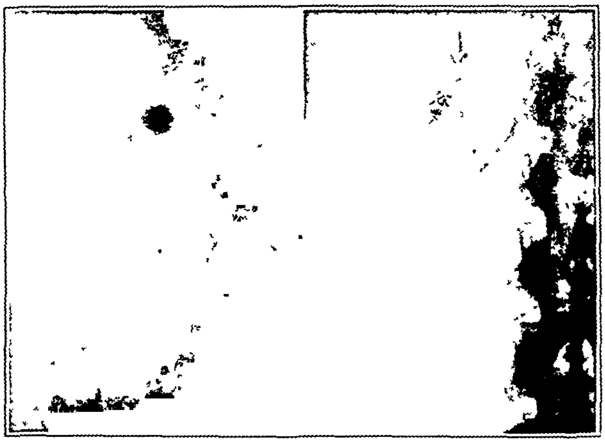

Fig. 5.—Posterior-anterior and anterior-posterior views of gallstones

Some method for the establishment of a diagnosis in cases of stones of no greater density than the surrounding kidney tissue is a very important phase of the diagnosis of kidney stones, especially in every case in which the clinical and urinary symptoms indicate a possible kidney calculus, although the usual roentgen-ray examination of the kidney has been reported negative (Fig. 9).

I have found that this can be accomplished by pyelography of the suspected kidney, the roentgenogram of which will show areas in the pyelogram of lesser density than that of the usual 15 per cent. sodium iodid solution used for the injection, and by their definite outline these areas will not be confused with incompletely filled pelves, blood clots in the kidney pelvis or tumors of the kidney.

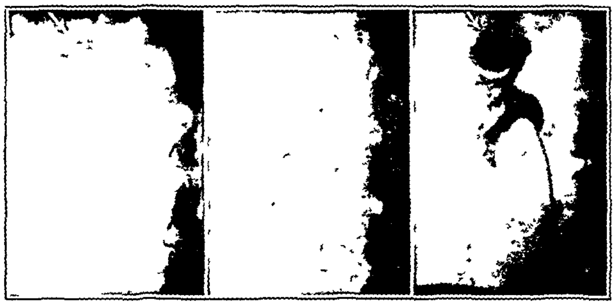

Fig. 6.—Anterior posterior and posterior anterior views of kidney stones, with pyelogram showing location of stones in the kidney pelvis.

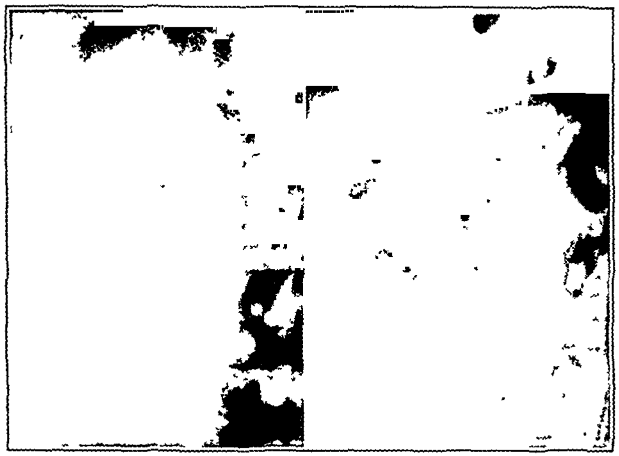
Pyelography, in fact, is one of the most important aids to the study of kidney stones and to the establishment of their differential diagnosis. Associated conditions in the kidney, such as hydronephrosis or urinary retention, may be determined by pyelography alone, or combined with a function test. A large pyonephrosis or hydronephrosis, in the presence of a long history of kidney stone, will be the deciding factor in determining whether or not a nephrectomy should be done.



A B

Fig. 7.—*A*, anterior-posterior view of kidney stones with pyelogram; *B*, location of stones

For a long time I have felt not only that a stone in the kidney should be verified by the loss of its shadow in the pyelographic medium which shows it to be within the kidney, but that a definite location of the stone should be made. It seemed probable that this could best be accomplished by using a solution of the opaque salt of a concentration that would permit the shadow of the calculi to be seen as a denser shadow through the pyelographic shadow. In order to determine the proper solution for this purpose, I placed kidney calculi in a quantity of solution corresponding to the usual capacity of the kidney pelvis, and submerged this in a water phantom of a depth equivalent to the depth of the kidney in the average patient. From roentgenograms made from this experiment, I found that when a water phantom 8 inches in depth and a stone of average density were used with a 3.5 per cent. solution of sodium iodid, a fair shadow of the solution was obtained, and the shadow of the calculi could also be easily seen (Fig. 10). A 7 per cent. solution completely obscured the stone. I realize that variations in the density of calculi, the depth of the kidney in individual patients, and the quantity of solution required to fill the pelvis, will make it necessary to vary the concentration of the solution somewhat for individual cases. This procedure is of great aid to the surgeon, as his method of approach for the removal of a stone can be made more readily and with greater precision if the location of a calculus in the pelvis of the kidney or in a calix has been definitely determined before operation.

I have not as yet had the opportunity to use this method in a large series of cases, but I feel that it will prove to be a valuable radiologic procedure in the study of kidney stones.

ABSTRACT OF DISCUSSION

Dr. L. T. LeWald, New York: I did not notice whether Dr. Nichols gave age incidence or not, but I have recently been interested in several cases in children of bilateral calculosis of the renal pelvis. I wonder whether he has had any cases in children as young as 3 years, and if so, what was done? We have one such case now. There have been various opinions expressed as to whether to leave the case alone surgically or whether to attempt removal of the stones. One urologist has very definitely stated that he thinks the child will survive longer without operative intervention. I, myself, feel that in some adult cases with bilateral calculi a successful outcome has been obtained by first removing the stone on the side that has less function, and after that kidney has been somewhat more restored to normal function, if that were the case, then attempting the removal of the calculus on the opposite side. I have seen a case, also, of calcification in a thrombus in the renal vein. This led to considerable confusion in diagnosis, being on the right side and in a jaundiced patient. We were cautious and suggested that, while it had the appearance in many ways of a biliary calculus, operative intervention had better be delayed until a pyelogram had been made. However, on account of the condition of the patient from the jaundice, immediate operation was undertaken with an anterior incision. The gallbladder was explored and found normal. The patient had some catarrhal obstructive jaundice and other serious complications, and died a few weeks later. The necropsy revealed a laminated concretion in the renal vein. In connection with the differential diagnosis postero-anteriorly and the reverse, I should like to ask Dr. Nichols whether he uses a standard, rather short distance in order to bring this out. If one uses a long distance, the shadows will not be proportionately different in their size, and I think that is a point to be borne in mind. Possibly, he uses a short distance to bring that out very distinctly, as shown in several of his cases. I should also like to ask whether the method of attempting to show stones of lessened density in the pelvis of the kidney might not also at times reveal a tumor or a blood clot or some other condition of the pelvis besides calculus.

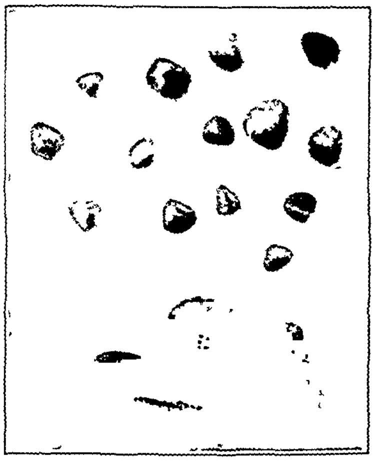


Fig. 8.—Stones removed at operation.

Dr. Daniel Eisendrath, Chicago: Our statistics as to the frequency of bilateral calculi agree with those of Dr. Nichols. Experience during the last ten years has taught the value of conservative operations and the necessity of limiting considerably the indications for operation. We refrain from operating if there are multiple calculi in both kidneys, unless one is located so as to block the outlet of the renal pelvis and interfere greatly with the function of that kidney. In the case of calculi in one or both ureters and also in one kidney, it is advisable to remove the ureteral calculi by nonoperative or operative means before the kidney operation is undertaken. A branching calculus or multiple calculi, filling more or less completely the pelvis and dilated calices, should either be left in situ or a nephrectomy considered, because we have very little to offer to prevent the reformation of calculi. Such a recurrence takes place in from 15 to 20 per cent. of all cases; hence we must give a guarded prognosis as to recurrence. The one positive indication for operations is when a single calculus blocks the outlet of the renal pelvis. We can employ the conservative operation of pyelotomy in nearly every case. I should like to emphasize the necessity of search for ureteral stricture or obstruction by an accessory vessel in every renal calculus case. In regard to the not infrequent concomitant occurrence of biliary and renal calculi, our experience agrees again with that of Dr. Nichols. Cholecystography and pyelography are indispensable aids in the differentiation of shadows due to biliary and renal calculi. Dr. Nichols' method, of using a 5 per cent. sodium iodid solution as a contrast medium in pyelography when the shadow is a very dense one and a more concentrated solution (12 per cent.) when the shadow is faint, is a very valuable contribution. It is easy to overlook calculi which give only a light shadow, and here the stronger solution often intensifies the shadow. We are able today, thanks to such methods as pyelography, to localize the shadow in respect to our plan of operation, whether it shall be a pyelotomy alone or a small nephrotomy, or the two combined. Much unnecessary injury to the kidney is thus prevented. Filling the pelvis and ureter with an opaque medium enables us to determine the degree of injury these structures have suffered and to understand why a calculus shadow can, at one sitting, be found in the renal pelvis and at the next one at the lower end of a greatly dilated ureter. These migrating calculi lead to many difficulties, unless a preoperative diagnosis has been made of the existence of marked dilatation of the ureter and the renal pelvis.

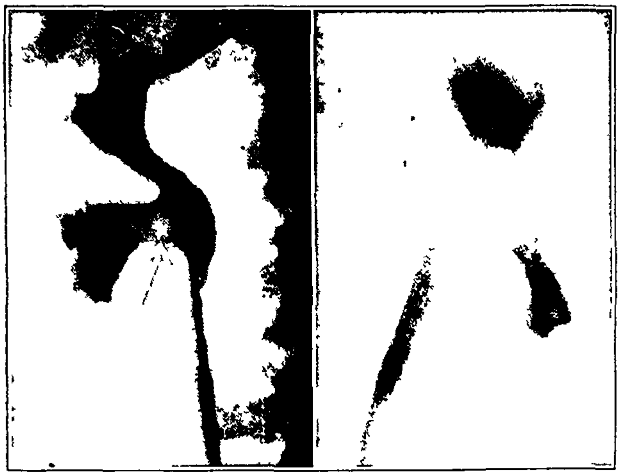

Fig 9.—Two cases of kidney calculi, in each of which the stone was of approximately the same density as the surrounding tissue.

Dr. Henry K. Pancoast, Philadelphia: I should like to ask Dr. Nichols whether he has had any experience with cases in which there was a stone on one side but pain on the opposite side. A few years ago this was considered possible in a definite percentage of cases. Now that our technic is so much improved, it is possible that this does not occur. Formerly we were missing a small stone on the pain side, or other procedures which now find some other lesion.

Dr. Edward S. Blaine, Chicago: I should like to ask Dr. Nichols whether he makes use of the lateral projection in the differentiation between gallstones and right kidney stones. An able presentation on the subject of gallstones by a British roentgenologist of large experience set forth forcibly this particular differential diagnostic procedure as being of greatest value. I should like to know whether Dr. Nichols uses it and if so whether he finds it of sufficient value to recommend it.

Dr. Dudley Mackey, Bloomfield, N. J.: We had a case of a kidney with three distinct pelvises. The first roentgenogram showed a large kidney. It was then decided to inject the kidney. Before injection three plates were made posterior and three anterior with no stone shadow in evidence. Care was used in the inspection of all plates to locate the shadow of the stone. Further examination showed a definite shadow but was not conclusive until the kidney was injected. By actual measurement of the shadow seen in the pyelogram, the stone was demonstrated. The other kidney in the same patient had two pelvises with distinct shadow suspicions of a stone, yet this was not positive until the pyelogram was made.

Dr. B. H. Nichols, Cleveland: As to the treatment of bilateral stone in a child of 3 years, I think it would depend on what the urinary symptoms showed. That is rather a decision for the surgeon to make. Our youngest patient with bilateral stone was 5 years old. If there were no urinary symptoms, that is, no hematuria or pyuria, I think it would be safe to delay operation for a time. We make our gallbladder and kidney films at a rather short distance, so that the variation in the size in the two positions is increased. Answering Dr. Blaine's question, we have given up the lateral view because if the tube is not exactly over the shadow, it will be carried one way or the other, as it is a considerable distance to the plate and it is difficult to show a stone through the patient laterally. Dr. LeWald's point is well taken, that when one sees a deformity in the kidney pelvis it might be a small papilloma in the kidney, which would give a rounded shadow and would look like a kidney stone. One cannot make a positive diagnosis of stone, but in the majority of cases blood clots and deformities of the kidney pelvis will not be misleading because one will see that the shape of the shadow corresponds to the same type of branching that we see in stones, or unless one sees a definitely rounded stone. By the law of probability, stones occur more often than papillomas. In answer to Dr.

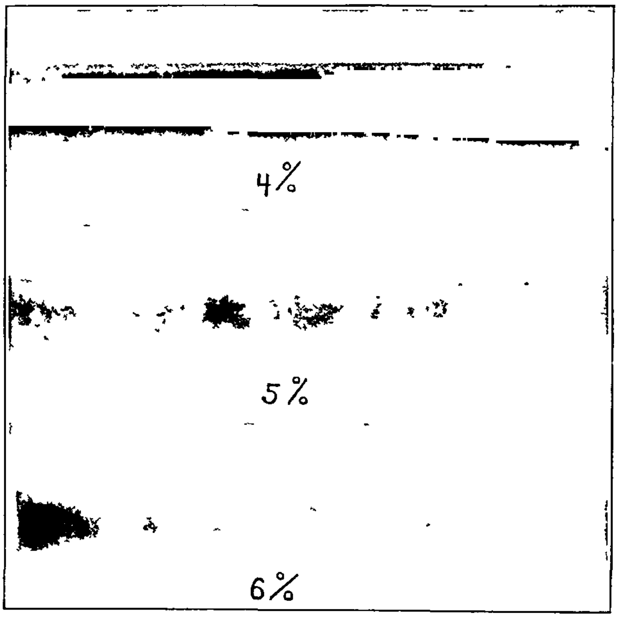

Fig. 10.—Water phantom study of calculi in sodium iodid solutions of varying densities.

Pancoast's question about pain on the opposite side, that is now, I think, almost negligible. Occasionally we see such a case, but it is of little importance, because the vast majority of patients with kidney stones have pain and tenderness on the side in which the stone is present.

ROENTGEN RAY IN THE DIAGNOSIS OF PERFORATED PEPTIC ULCER *

R. T. VAUGHAN, M.D.
AND
WILLIAM A. BRAMS, M.D.
CHICAGO

Air, free in the peritoneal cavity, has long been considered a valuable sign in the diagnosis of perforations of the gastro-intestinal tract, but this important sign has not gained the popularity that it deserves because of the uncertainty with which its presence was formerly elicited by percussion, particularly when the air was present in small volume.

The possibility of demonstrating free intraperitoneal air by the roentgen ray suggested itself to us as a more accurate and reliable method than by percussion of the liver dulness. There was also the possibility that the air could be visualized at a much earlier stage after perforation than by the older method. A study of the literature on this subject revealed several brief references to the roentgen-ray detection of air in the peritoneal cavity, but no reports could be found in which the sign was studied in a large series of cases in relation to the incidence and time of appearance after the perforation occurred.

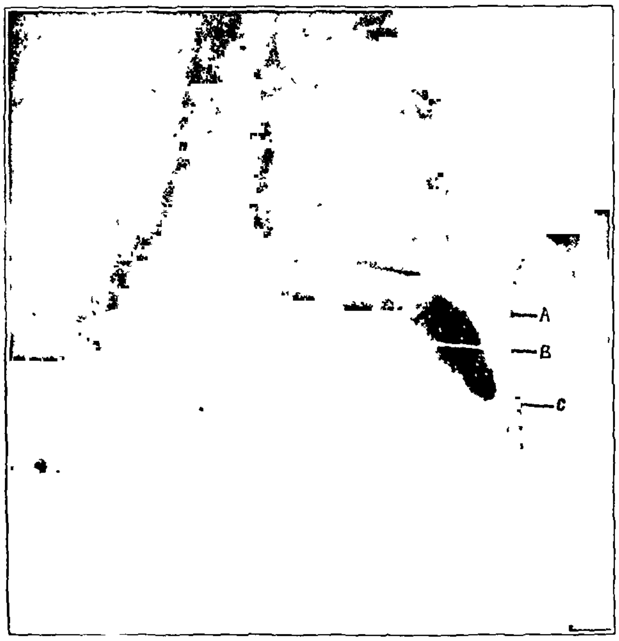

Fig 1.—Spontaneous pneumoperitoneum between diaphragm, *A*, and upper surface of liver, *B*, *C*, horizontal fluid level.

Cases of ruptured gastric and duodenal ulcers in which the intraperitoneal air was visualized with the roentgen ray were reported by B. Bager, H. Schottmuller, H. A. Dahm, W. Weiland, and H. Wessler and L. Jaches. These authors reported only one or two cases, and H. Assmann, who described four such instances, gives only scant attention to this sign. G. H. Copher recently reported a series of five cases of ruptured ulcer in which it was possible to visualize air in the peritoneal cavity. In a previous communication we reported a series of fifteen cases of proved acutely perforated gastric and duodenal ulcers, in thirteen of which free intraperitoneal air could be seen with the fluoroscope. This intra-abdominal air is not limited to perforated peptic ulcer but may occur after rupture anywhere in the gastro-intestinal tract. R. Reinecke reported a case of gangrenous appendicitis that had ruptured and that had resulted in subphrenic abscess in which free air was seen between the diaphragm and upper surface of the liver. This zone of air was seen in the foregoing location when the patient was in the upright position and disappeared when the posture of the patient was changed. L. Kenez found a similar picture after a perforation of a tuberculous ulcer of the small intestine, and a similar result was obtained by H. Popper after a rupture of the bowel.

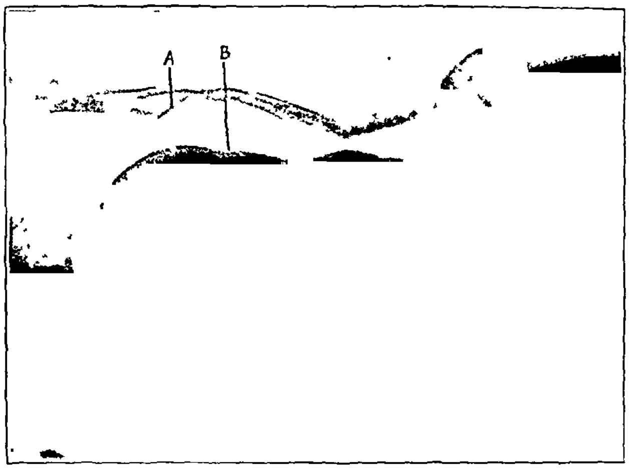

Fig. 2.—Patient on left side, showing free air between lateral wall of abdomen, right surface of liver, *B*, and diaphragm, *A*.

These few reported observations in which free intraperitoneal air was found after perforations of the gastro-intestinal tract other than of the stomach or duodenum do not detract substantially from the value of the sign in perforated peptic ulcer, as all of the conditions in which the phenomenon was observed proved to be surgical emergencies demanding immediate operation. The practical importance of this sign lies in the fact that, while it may occur in any perforation of the gastro-intestinal tract, the vast majority of these perforations occur either in the stomach or in the duodenum. Our own observations include a number of cases of perforated appendicitis that were examined by fluoroscopy, but we were unable to observe free intraperitoneal air in any of them.

Our material consists of twenty-nine cases of acute perforation of gastric and duodenal ulcer, all of which were examined by fluoroscopy as well as by the other usual method before operation. All of them were proved to be perforated ulcer of the stomach or duodenum, either at operation or at necropsy. The method of fluoroscopic examination is very simple and requires no preparation or use of a contrast meal. The patient may remain on the hospital cart during the examination, and the entire procedure need not take more than a few minutes. There is no danger or discomfort to the patient, no delay to the operation, and the information gained is well worth the effort exerted in eliciting this sign.

---

* Read before the Section on Gastro-Enterology and Proctology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

The visualization of the intraperitoneal air is possible in the early stages because the air seeks the highest point in the abdomen so that with the patient in the upright position, either sitting or standing, the air bubble will be observed between the under surface of the diaphragm and the upper surface of the liver. The same principle enables us to see the air between the outer surface of the liver and the right abdominal wall when the patient is on his left side, and between the spleen and the left abdominal wall when he is on his right side. We have been able to see the air bubble in the pelvis by placing the patient in the Trendelenburg position. It is not necessary, however, to turn the patient to all these positions, as one or two postures will be quite sufficient. We have found the dorsal and left lateral positions sufficient for diagnosis, and we have often employed the sitting posture without discomfort to the patient. It is frequently possible to detect a fluid level if both air and fluid are present, and a splashing may be detected if the patient is shaken. The origin of the air seen in the peritoneal cavity in these cases is from the stomach and comes from the gastric "air bubble" normally present in this organ. But little air, a few cubic centimeters, is all that is required to be visualized by the fluoroscope as it all tends to collect in one place. The fact that the air is free in the peritoneal cavity and the characteristic outline and location of this air may be determined by changing the position of the patient, when it will be observed that the air bubble shifts from its previous location to the highest point in the abdomen as determined by the new position.

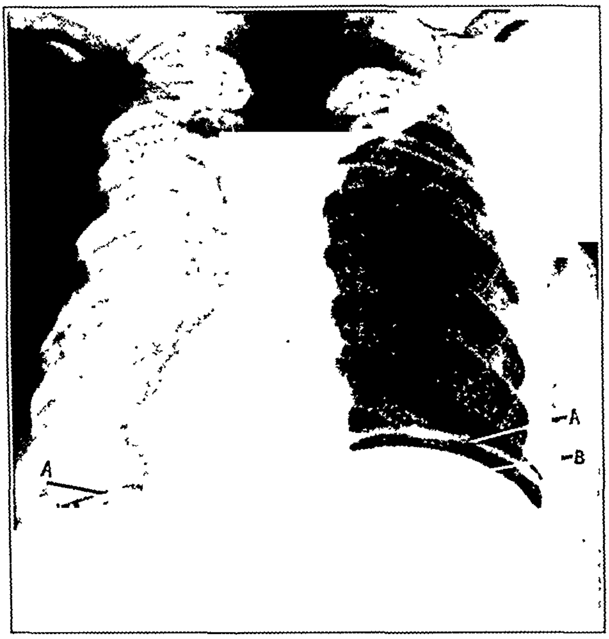

Fig. 3.—Patient in upright position, showing free air between diaphragm, *A*, and upper surface of liver, *B*, on right side, and between diaphragm and abdominal viscera on left side.

The free air as described was seen in twenty-five of the twenty-nine cases so studied, or in 86.2 per cent. of our series. Most of the cases were of a few hours' standing, and one case showed a distinct air zone two hours after the occurrence of the perforation. The value of this sign lies, therefore, not only in the fact that it aids us to recognize acute perforation of a gastric or duodenal ulcer but also in that it enables us to make a very early diagnosis, thus permitting the surgeon to operate earlier and giving the patient a better chance for recovery.

SUMMARY

1. Free air in the peritoneal cavity is pathognomonic of gastro-intestinal perforation and was found on fluoroscopic examination in 86.2 per cent. of a series of twenty-nine proved cases of acute perforation of gastric or duodenal ulcer.

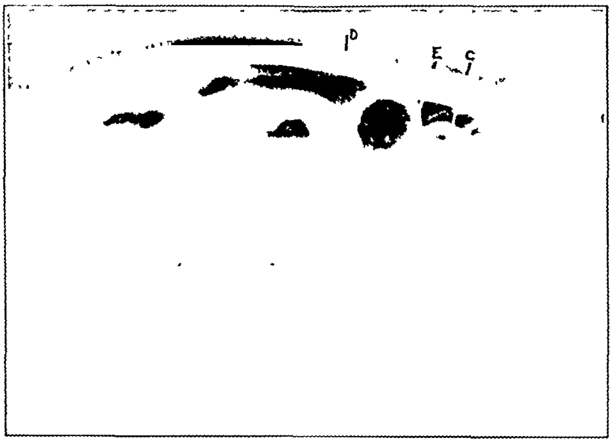

Fig 4.—Patient in supine position, showing free air between anterior abdominal wall, *D*, coils of intestine, *E*, and fluid level, *C*.

2. This free air is easily seen on fluoroscopic examination without previous preparation or use of a contrast meal.

3. The sign appears in the earlier stages of perforation and was present two hours after the onset of the trouble in one of our cases.

4. The free air is recognized by observing a narrow, sickle shaped zone of freely shifting air between the viscera and the abdominal wall or between the diaphragm and the upper surface of the liver. The air changes location with change of posture of the patient.

5. The procedure is apparently without harm and does not produce discomfort to the patient. The information gained is easily worth the few minutes that it takes to examine the patient in the manner described.

6. The sign is not offered as a substitute for the diagnostic procedures usually done in these cases, as a diagnosis can be made in most instances on the history and physical examination. The sign is offered as a valuable addition to our diagnostic armamentarium in the recognition of acutely perforated gastric and duodenal ulcer, because it is practically pathognomonic.

Cook County Hospital—2819 Logan Boulevard.

ABSTRACT OF DISCUSSION

Dr. John D. Dunham, Columbus, Ohio: The speakers called attention to a very important addition to our methods of diagnosis. The interpretation of these methods offers difficulties in certain instances; for example, in paralytic ileus the differentiation of air within and outside the intestine would be somewhat difficult. There are objections in the way of interpretation that might be mentioned. One case in particular illustrates the point: A young woman was brought into the hospital with acute abdominal pain, some distention and a rigid abdomen. The history justified the conclusion that she had undoubtedly rupture of one of the viscera of the stomach or of the duodenum. Free air in the peritoneal cavity was demonstrated by a roentgenogram. At the laparotomy, it was found that there was an opening in the uterus. A metal catheter had been used to produce abortion. A patient with symptoms of rupture from gastric or duodenal ulcer, when first seen by the physician, has usually been ill for some time. Further time must elapse before the patient reaches the hospital or the roentgenologist. The question arises as to whether this method of examination does not dangerously delay surgical intervention. Is it not true that change of posture is liable to introduce more than air into the abdominal cavity? The percentage of recoveries in the treatment of ruptured viscera depends on the speed with which operation is undertaken. It occurs to me that, unless a patient is seen within one or two hours after the onset of symptoms, the older methods of observation must be depended on, such as history taking, palpation and leukocyte count, in order that the patient may not be unduly held off from treatment.

Dr. R. T. Vaughan, Chicago: We have already stated that operation is not delayed by this procedure. On the way from the ward to the operating room, the patient passes the roentgenray department, where he is run before the fluoroscope while still on the hospital cart. Not five minutes is required for this examination, whereas it takes our nurses usually from twenty to thirty minutes to get the operating room "set up" for an emergency operation. What do we do with the 15 per cent. of cases that show no gas bubble? In most of them, especially those with severe symptoms and well marked signs, the diagnosis can be made readily without the gas bubble, as it can, too, when the bubble is present. In some cases the diagnosis is made only by exploratory laparotomy, when the symptoms present justify no further preliminary diagnosis than an acute surgical condition of the abdomen. There are occasionally cases of perforation with still milder symptoms, and it is difficult or impossible to say whether they are surgical or nonsurgical at first examination. On three patients in whom one of the diagnostic possibilities considered was perforated ulcer, either very tiny or secondarily closed by omentum or food particle, I have tried a new procedure with a positive result in one case. As fluoroscopy showed no free gas bubble, on admission to the hospital the patient was put in the lateral position for several hours. In this position the gastric gas bubble lies in the pyloric portion of the stomach and all gastric fluid in the cardia and fundus. If a pyloric or duodenal perforation is present, only gas should escape from it, and the danger of leakage of fluid through the perforation should be minimal. After the lapse of eight hours, a tiny but unmistakable peritoneal gas bubble was discovered in this patient. Laparotomy was immediately performed, the tiny gastric perforation opening closed, and the patient saved. This patient's temperature was only a trifle over 99 F.; leukocyte count was 10,000; there was abdominal discomfort rather than actual pain, and there was only a suggestion of rigidity. The other two patients recovered without operation or a gas bubble being discovered, so that the exact diagnosis in their cases is not known.

Rubber Gloves.—The wearing of sterilized rubber gloves when operating is the greatest improvement in surgery since Lister discovered the cause of sepsis.—Sir John Bland-Sutton, President, Royal College of Surgeons of England.

ADENOMATOSIS, OR THE DIFFUSE ADENOMATOUS GOITER *

J. EARL ELSE, M.D.
Assistant Professor and Chairman, Executive Committee, Department of Surgery, University of Oregon Medical School
PORTLAND, ORE.

Under the term adenoma, there is described in the literature two definite distinct pathologic entities, adenomatosis, or the diffuse adenomatous goiter, and true adenoma, which is a definite encapsulated growth beginning from a single point and answering all the requirements of the benign tumors.

Adenomatosis of the thyroid is characterized by a diffuse new formation of acini usually involving the entire thyroid gland, beginning with the fetal type without secretion, but later assuming the adult or colloid type, and giving rise to no symptoms at first, but later to those of pure hyperthyroidism.

Wilson, in 1913, briefly described this condition and applied the term adenomatosis. Goetsch, in 1920 and 1921, described the early stage under the term diffuse adenomatosis, but referred to the new formation of acini as "an abortive attempt at the formation of young small alveoli." Plummer, in his writings, has grouped adenomatosis with the adenomas, treating them as a single entity. In addition to these references, I have referred to this condition in several communications, but up to the present there has been no description of the disease tracing it through its entire course.

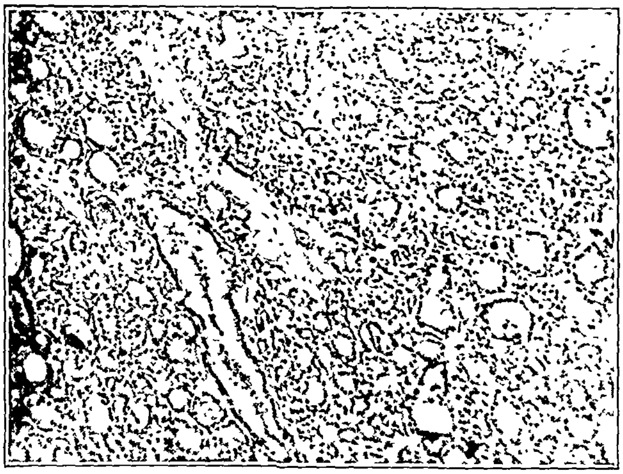

Fig. 1.—Early adenomatosis: thyroid only slightly enlarged, with no nodules; diffuse new formation of acini; fetal and adult acini present throughout thyroid.

PATHOLOGY

The pathologic picture varies with the stage of the disease.

Early Adenomatosis.—The thyroid gland is moderately enlarged, the surface is smooth, and the consistency is somewhat increased over the normal. On section, the cut surface presents a more dense appearance than in the normal gland; and, while some colloid is present, there is not the same semitranslucent appearance characteristic of the normal thyroid. In the early stage the gland is homogeneous, and nowhere is there to be seen any tendency toward nodular formation. On microscopic examination (Fig. 1), it is found to contain both fetal acini and apparently normal or colloid acini. Between these two types of acini are found all possible variations, the appearance being indistinguishable from that of the mixed adenoma. In other fields there may be an apparent increase in the interstitial cells. In some areas these cells are arranged in masses, many of them showing the definite beginning of acinus formation. It was these areas that Goetsch referred to as being abortive attempts at the formation of young small alveoli. A study of a series of cases, however, demonstrates that this is not an abortive attempt, but is instead the real beginning of the new acini.

---

* From the goiter clinic of the University of Oregon Medical School and the pathologic laboratory of Good Samaritan Hospital.

* Read before the Section on Surgery, General and Abdominal, at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

Late Adenomatosis.—The gland shows a marked enlargement. The surface is more or less lobulated, often with very definite nodules projecting. On cut section (Fig. 2), the nodular arrangement is still more manifest. On close observation, these nodular masses are seen to be made up of groups of acini distended with colloid. Many of these masses have a thin, membranous capsule and can be enucleated, presenting an appearance not unlike that of an adenoma, but differing from an adenoma in that the capsule is only a thin membrane instead of the well developed capsule of the adenoma (Fig. 3). Between these nodules is found compressed thyroid tissue. In some places degeneration has taken place, while in other areas there may be marked connective tissue proliferation, marking the site of a former degenerative process or a hemorrhage. Sometimes cystic formation is present, while hemorrhagic areas, either into some of the nodules giving a sharply circumscribed hemorrhagic mass, or infiltrating between the nodules, may be found. On microscopic examination of the colloid nodules, the picture is very similar to that seen in a colloid adenoma. Sections made from the tissue between the nodules often show the same type of structure, differing only in the amount of colloid present in the acini. Solitary lymph follicles may be found.

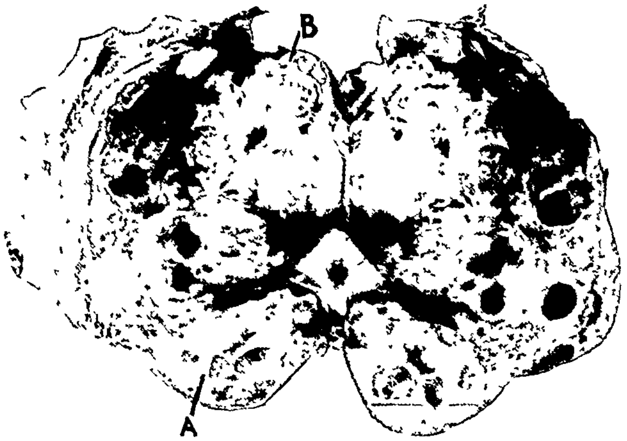

Fig 2 —Adenomatosis cut surface showing adenomatous nodules *A* unencapsulated nodules, *B*, nodule with thin capsule, to be contrasted with Figure 3

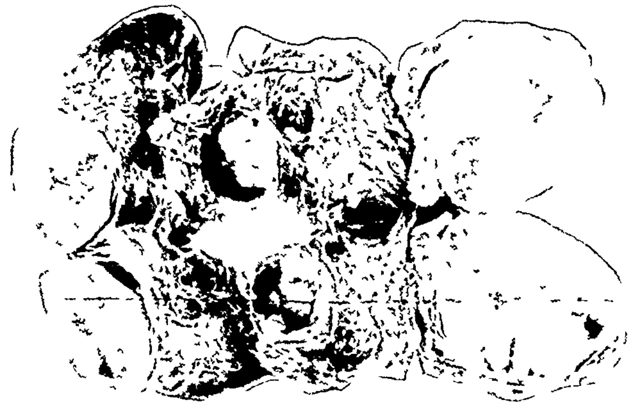

Fig 3 —Multiple adenomas three adenomas in one lobe; definitely encapsulated Difference from Figure 2 may be noted.

The blood supply in adenomatosis is increased, and in many cases there is a very definite increase in the collateral circulation.

PATHOGENESIS

It is impossible to trace any one given thyroid gland through its course from the beginning new formation of acini to the development of colloid adenomatosis, but by studying a series of cases, the method of development can be fairly well ascertained. The very first evidence of the beginning of an adenomatosis is the formation of undifferentiated cells in masses (Fig. 4). These cells are probably identical with those described by Wolfler as interstitial cells. They do not differ from the appearance of the cells seen in the beginning of the development of new acini within old acini, as seen in compensatory hyperplasia (Fig. 5). Just as in well developed compensatory hyperplasia one sees in the center the undifferentiated cells, external to this the fetal acini, and next to the wall of the parent acini the colloid acini, so in adenomatosis (Fig. 6) one finds first a group of the undifferentiated cells, then the newly formed acini of the fetal type, and then the acini that are taking on the power of secreting colloid. From this stage the process goes on to the stage at which the acini are overdistended with colloid In some areas the development becomes more rapid, pushing the neighboring acini to one side, thus giving an appearance similar to that seen in adenomas, but differing in that there is either no capsule at all or usually only a thin membranous capsule. Sometimes there is a fairly definite capsule about some of the nodules, but rarely does it attain a thickness or appearance resembling that seen in the adenomas.

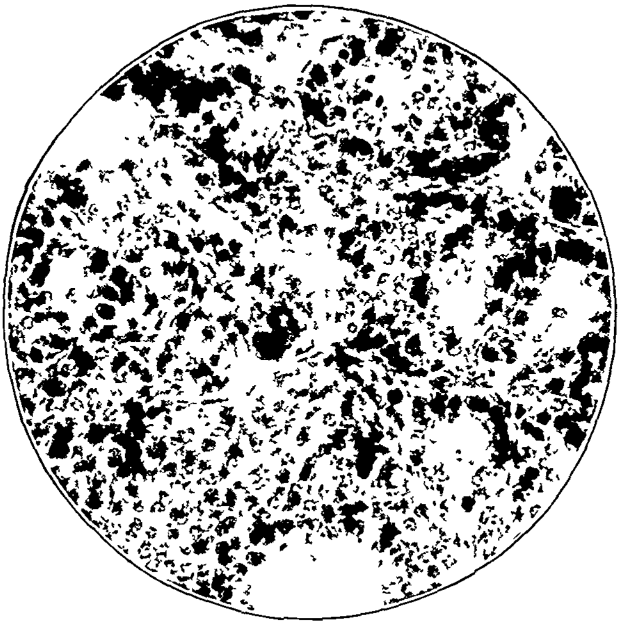

Fig 4 —Adenomatosis, showing transition from undifferentiated cells to fetal acini.

Taking the picture as a whole, it gives one the impression of a diffuse new acinous formation in which certain areas have developed more rapidly than others, thus producing the nodular effect.

The origin of the cells from which the new acini spring is not known. A study of a series of cases of adenomatosis suggests three different theories: (1) congenital; (2) origin from the Wolfler or interstitial cells; (3) a hyperplasia of the cells lining the normal acini.

According to the first theory, either the acini are present at the time of birth, being an abnormal fetal development, or else there are present certain undifferentiated cells at birth not normally found in the thyroid gland from which the acini develop. According to the second theory, the new acini form from the interstitial cells of Wolfler, which are normally found in the thyroid gland. The function of these cells is not definitely known, but it may be that they are for the purpose of regeneration in thyroids that have been partially destroyed or removed, or in thyroids secreting an insufficient amount of thyroxin. In other organs, the regenerative ability is usually present. In the liver, for example, where there has been a slow destruction of the liver lobules, as in cirrhosis, there is often a new development of liver substance in adenomatous-like masses sufficient to carry on the liver function so long as the blood supply is not interfered with. This new formation in the liver probably develops from the bile radicles. The thyroid gland, not having ducts through which the secretion may be discharged and from which regeneration may take place, may have instead the so-called interstitial cells for this purpose, and from these, according to this theory, may come a diffuse atypical acinous formation.

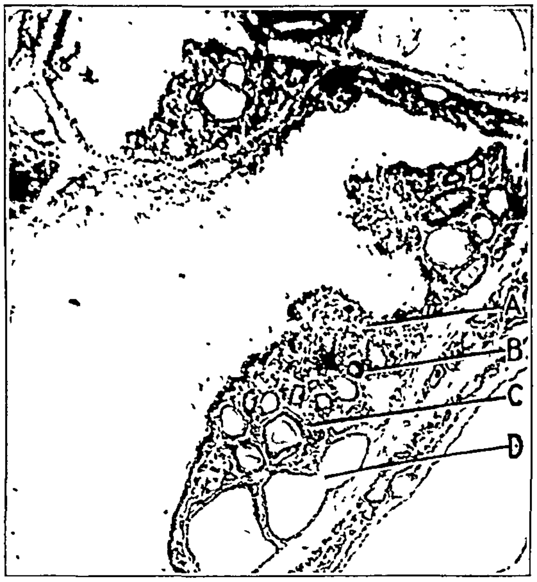

Fig 5 —Compensatory hyperplasia, showing manner of the development of new acini within old acini: *A*, undifferentiated cells; *B*, fetal acini; *C*, intermediate cells; *D*, adult acini.

The third theory is that a new formation of acini similar to that seen in compensatory hyperplasia may develop from the cells lining the old acini, but outside the walls of these acini instead of inside, as in compensatory hyperplasia.

It would appear from the glands studied that the theory that these new acini develop from the interstitial cells was more tenable than any other theory; however, without the opportunity of studying a large number of thyroid glands of children or of the age of adolescence, one cannot be certain that there may not be some which show the characteristic findings of adenomatosis from birth. Accepting the theory of the development from the interstitial cells as being correct, the source of the interstitial cells is the next problem in pathogenesis. These may be congenital, put there for the purpose of regeneration, as stated, or it may be that they spring from the epithelial cells of the acini.

ETIOLOGY

Three theories of causation are apparent: (1) that it is congenital; (2) that it develops from uncured adolescent goiter; (3) that it is developed as the result of a stimulus from the mild hypothyroidism due to iodin deficiency in the food and drink intake.

1. The congenital theory has already been discussed under pathogenesis.

2. The patients having adenomatosis that I have seen may be divided into three groups so far as a history of adolescent goiter is concerned. The first group, by far the largest, gives a history of having had an adolescent goiter. The second group is uncertain whether a goiter was present or not during the adolescent period, and the third group, which is the smallest, is certain that there was not a goiter; but many if not all of these patients may be mistaken. The adolescent goiter probably leaves the thyroid in a somewhat atypical state with a reduced reserve, so that when increased demand is thrown on the thyroid gland in later life the changes characteristic of adenomatosis take place. Patients with other forms of goiter in adult life gave the same history regarding adolescent goiter; hence, it appears probable that an uncured adolescent goiter may predispose to the development of all types of adult goiter.

3. It is known that mild hypothyroidism due to a deficient iodin intake may result in: (1) an oversecretion of colloid, for the thyroid in its attempt to secrete more thyroxin may secrete too much colloid; (2) a hyperplasia of the cells within the acini, as seen in hyperplastic adolescent goiters, in which the hyperplasia may be either diffuse or localized and in the latter case often mistaken for adenomas, and (3) the new formation of acini, as seen in compensatory hyperplasia. To summarize our knowledge of the etiology, it would seem that a simple nontoxic goiter, as the goiter of childhood, the adolescent goiter, or the colloid goiter of adult life, but more especially the adolescent

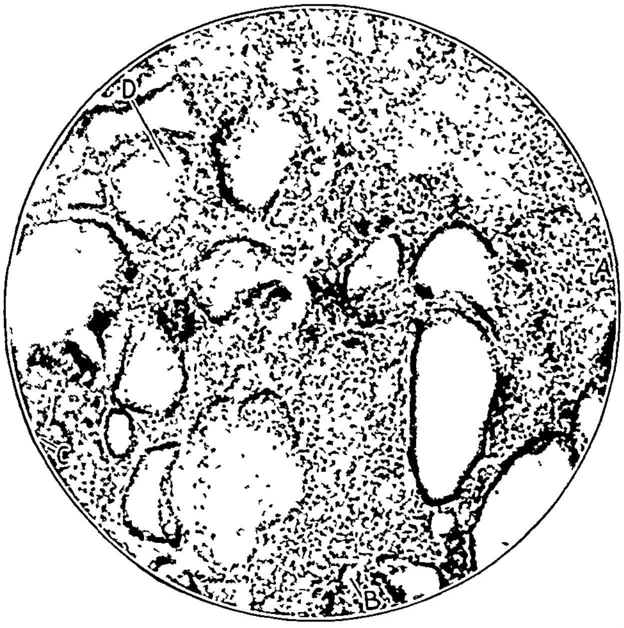

Fig 6 —Adenomatosis: *A*, undifferentiated cells; *B*, beginning fetal acinus formation; *C*, intermediate acini; *D*, adult acini

goiter, predispose to the development of adenomatosis, and that an iodin deficiency in the food intake is an important factor.

SYMPTOMATOLOGY

Early in the development of this disease, the only evidence of the presence of an adenomatosis is a slight enlargement of the thyroid gland. It is probable that considerable time elapses between the beginning of the adenomatosis and the beginning of the symptoms in those that become toxic, the same as occurs in true adenomas. The onset of the symptoms is insidious, so that the patient does not come seeking treatment until the symptomatology has become fairly definite. At this time the most frequent complaints are tiring easily, nervousness, shortness of breath, tachycardia and palpitation. The appetite is usually very good, while the weight is variable, some patients losing and others having no change. There is never a history of acute symptoms as seen in exophthalmic goiter. The most common clinical findings are tachycardia, tremor, moderate rise in the basal metabolic rate, moist skin and palms. The size, shape and consistency of the thyroid vary with the stage of the disease.

Early the gland is only moderately enlarged and smooth; later it may be markedly enlarged and nodular. The largest goiters that we have seen belonged to this type. Increase in the systolic pressure occurs, followed gradually by an increase in the diastolic. The blood pressure of adenomatosis, like that in toxic adenomas and compensatory hyperplasia, differs from that in exophthalmic goiter in that the diastolic pressure is usually not lowered or, if lowered, is lowered but slightly, while the systolic pressure rises, thus giving an increase in the pulse pressure characteristic of toxic goiter. With the development of tachycardia and hypertension, cardiac hypertrophy takes place.

DIAGNOSIS

The diagnosis of hyperthyroidism is made on the history of tachycardia and palpitation, increased nervousness, tiring easily, increased sweating, increased pulse pressure accompanying a tachycardia, and an increase of the basal metabolic rate. The differential diagnosis between adenomatosis and toxic hyperplastic (exophthalmic) goiter is made, first, on the history and, secondly on the clinical symptoms. In adenomatosis there is usually a history of a goiter having existed for a considerable time. The onset of the symptoms is insidious. The most common complaints are tachycardia, palpitation, tiring easily and getting out of breath easily. There is a good appetite and usually little disturbance with the weight, unless the patient is seen late in the disease. On physical examination, the goiter is found to be small and smooth and fairly firm early in the disease, and large, soft and lobulated late in the disease. There is an increase in pulse pressure resulting from a rise in the systolic pressure as a late sign. The diastolic pressure rises late in the disease but does not keep pace with the rise of the systolic pressure. Tremor is present. There is no exophthalmos, lagging of the upper lids, or hyperthyroid crisis. The basal metabolic rate is moderately increased, being found usually between a plus 30 and a plus 50.

In the toxic hyperplastic goiter (exophthalmic) as seen in the first attack, there is a definite tachycardia with fibrillation in the extreme cases, well marked tremor, evidence of a loss of weight, and lagging of the upper lids, with exophthalmos in the majority of patients. The skin is always moist, and the palms are sweaty. The patients give a history of being warm without a rise in temperature. Many of them want the living room cooler than other members of the family, and fewer covers at night. In a well marked attack, the basal metabolic rate is fairly high, usually 50 or more. The patients are usually nervous, and many of them talk rapidly. In secondary attacks, the findings are not so definite. There is an increase in the pulse pressure, resulting from a lowering of the diastolic, rather than to a raising of the systolic pressure. The systolic pressure may be normal, below normal or occasionally above normal. The diastolic pressure is rarely above normal.

A differential diagnosis between adenomatosis and toxic adenoma must be made by palpitation of the thyroid, as the clinical manifestations are the same. In the adenomas, there is one or at most two or three definitely isolated nodules. In adenomatosis, at first the gland shows only a diffuse enlargement without any nodular formations. Later the gland presents a lobulated sensation to the examining fingers instead of the definite isolated nodules of adenomas. In some instances in which there has been a rapid development in some areas there may be fairly definite nodules, but these are always accompanied by a more or less lobulated gland.

PROGNOSIS

The prognosis varies with the intensity of the disease and the length of time elapsing after the toxic symptoms develop. The prognosis of cure with proper treatment so far as the hyperthyroidism is concerned is usually good. Early in the disease a good prognosis for the relief of symptoms may be given, but after definite cardiac hypertrophy has developed, after definite hypertension has been established, and after the patient has become distinctly nervous, the prognosis, so far as relief from symptoms is concerned, becomes less favorable.

In the cases showing a marked hypertension, there is practically always a reduction in the blood pressure following operation, but it usually does not go entirely back to normal. A damaged heart muscle remains a damaged heart muscle. A badly disordered nervous system resulting from a prolonged or a pronounced hyperthyroidism may not become entirely normal again. To give a good prognosis, the proper treatment must be instituted early.

TREATMENT

A cure can be obtained in only one way; that is, early adequate removal of thyroid substance. Like all patients with hyperthyroidism, each patient must be carefully studied in order to determine the treatment for that individual. Patients seen fairly early will stand the radical operation well. It has been our experience that because of the increased collateral circulation, ligation of the superior thyroid poles is of little value. Patients in whom the condition is moderately severe are put in bed for a few days previous to operation with an ice collar about the neck, sufficient sedatives, barbital or morphin, to keep them quiet, and digalen, 10 minims (0.6 c.c.) intravenously or intramuscularly every four hours if the pulse is over 120. In the severe cases we use the roentgen ray rather than superior pole ligation to decrease the activity of the thyroid in order to make the patient a safe risk. On the night before the operation, the patients are always given barbital or morphin. There is no preoperative preparation. The patient's rest is not disturbed, even by giving an enema on the morning of operation. If the patient is found excessively apprehensive or nervous, the operation is postponed.

The operation must be a subtotal double lobectomy. We leave only the posterior capsule and a thin layer of thyroid gland adherent to it. If more is left there is danger of recurrence. It is possible with this type of operation that there may be an occasional patient who will show the evidence of hypothyroidism for a short time, but we have never seen such a case. With a careful study of each individual case and with the proper preliminary preparation of the patient, there should be only a very slight mortality.

CONCLUSIONS

1. Adenomatosis is a definite pathologic entity differing from adenoma in that the process is diffuse and does not have a true capsule.
2. Adenomatosis produces a hyperthyroidism of the cardiovascular type.
3. It is important to differentiate between adenoma and adenomatosis because the former requires simple enucleation of the tumor growth, while the latter requires subtotal double lobectomy.

PRESENT-DAY SURGICAL TREATMENT OF DISEASES OF THE THYROID GLAND*

JOHN DE J. PEMBERTON, M.D.
ROCHESTER, MINN.

In 1866, Samuel D. Gross[1] said:

> When the tumor resists our curative efforts and endangers suffocation, it has been proposed to afford relief by extirpation, but the question arises, is such a procedure proper or justifiable? In a word, can the thyroid, when in a state of enlargement, be removed with a reasonable hope of saving the patient? Experience emphatically answers, "No." . . . No honest and sensible surgeon, it seems to me, would ever engage in it.

Since this declaration there has been prodigious progress in the field of surgery, and probably in no branch has the advance been greater, more rapid or more secure than in that dealing with diseases of the thyroid gland. To have reduced the operative mortality in a period of less than seventy years from a state of prohibitive operative hazard to barely 0.5 per cent. is a record of surgical achievement worthy of just pride.

The evolution of surgical treatment of the thyroid gland has proceeded along two main lines: the perfection of the technic of the operation, and the control of hyperthyroid cases.

From the knowledge revealed by the discovery of the parathyroid bodies and their function, and by the discovery that myxedema resulted from the loss of function of the thyroid gland, through the efforts of many surgeons, notably Billroth, Kocher, Mikulicz, Halsted,[2] C. H. Mayo and Crile, the operative technic was developed and standardized. The perfection of the technic resulted in practically eliminating the danger of operating on goiters without hyperthyroidism. In the Mayo Clinic in the year 1924 there was not a single death following 667 subtotal thyroidectomies in 667 cases of simple goiter.

However, the perfection of the technic solved only part of the problem of surgical treatment of goiter with hyperthyroidism, for in this type of goiter are the additional operative hazards of acute hyperthyroidism and the debility of the patient incident to hyperthyroidism or to the presence of visceral degeneration, which in the past have too often marred the success of the technically flawless operation.

The demonstration by Plummer that "toxic" goiter occurs as two distinct entities, exophthalmic goiter and adenomatous goiter with hyperthyroidism, was not only of academic interest but also of fundamental importance in paving the way for a more rational method of treatment. The additional operative hazards in the two are the same, but each disease had to be attacked along entirely different lines.

EXOPHTHALMIC GOITER

Formerly, the most baffling and discouraging problem in the management of exophthalmic goiter was the frequent occurrence of postoperative hyperthyroid crises. Although many measures have been advocated to check the progress of the reaction when once induced, not one has proved effectual. Fortunately, it was early recognized that hope lay in prevention, and efforts were directed at means of reducing the intensity of the hyperthyroidism and of affording protection to the patient. Thus, it was learned that during certain phases, when the degree of hyperthyroidism is greatest, by substituting minor surgical procedures, such as ligation, at a diminished hazard, the condition of the patient could be so greatly improved thereby that the thyroid gland could be resected later without the risk of an acute reaction. For the same purpose the operation might be divided into many stages. Other means advocated for the rehabilitation of the patient included the application of roentgen rays and radium to the thyroid and thymus glands, injection into the thyroid gland of boiling water and various drugs, such as phenol (carbolic acid) and iodin, and the employment of general measures of rest, high calory diet, forced fluids and the like. Likewise, there were developed numerous refinements in surgical management, comprising chiefly the avoidance of prolonged general anesthesia and the use of special types of anesthetics, the preoperative administration of drugs, such as morphin and scopolamin, and the performance of the operation in the patient's bed, all designed for the protection of the patient.

This advance in the management of patients with exophthalmic goiter had an important and far-reaching effect on the surgical treatment of goiter. Up to this time the relatively high operative risk deterred many patients with exophthalmic goiter from submitting to operation until other methods of treatment had been tried without success, that is, until late in the course of the disease, after the development of visceral degeneration, which in turn definitely handicapped the surgical treatment of exophthalmic goiter by increasing the operative hazard and by diminishing the chance for complete cure. With increasing knowledge of the disease, by the employment of preliminary surgical procedures, and by better care of the patient, the operative mortality was gradually lowered to a point nearly comparable to similar surgical procedures of equal magnitude, so that patients with exophthalmic goiter began to seek surgical treatment before the dis-case had wrought permanent damage. Thus, one of the additional operative risks was partially removed by the patient.

[2] Halsted, W. S.: The Operative Story of Goiter, Johns Hopkins Hosp. Rep. **19**: 72-258, 1920.

While the results obtained by the perfection of this method of management must be considered a great victory, and at once gave to surgery the leading rôle in the treatment of exophthalmic goiter, there remained several obvious disadvantages and failures in the method itself. In the first place, the method did not completely eliminate the danger of acute postoperative crises, as occasionally and often unexpectedly a death attributable to this cause would quickly supervene on a minor procedure, such as ligation or injection of hot water into the gland. In the second place, it imposed a definite restriction on the operability, as a certain proportion of the patients who have had ligations and are allowed to go home for a period of restoration do not return for the completion of the operation. There are three chief reasons for their not returning: 1. In certain cases, the ligations may fail to check the progress of the disease and the patient dies. 2. In other cases, the improvement is so marked that the patient does not consider the necessity for further surgical treatment until after several relapses, when he has lost the benefit of an early operation. 3. In still others, the patients do not return for financial or other reasons. There are, also, a group of patients admitted in a state of crisis, who die before they can be prepared for operation. Finally, from the standpoint of the patient's comfort and mental strain, not to mention the economic loss, the disadvantages of multiple operations are obvious.

In the Mayo Clinic in March, 1922, Plummer[3] instituted the administration of compound tincture of iodin (Lugol's solution) to patients with exophthalmic goiter under preparation for surgical treatment. Previous to this, the general conception of the nature of the hyperthyroidism in exophthalmic goiter was that the body tissues were saturated with iodin elaborated by the thyroid gland. Hyperthyroidism and hyperiodism were spoken of synonymously, and so the administration of iodin to patients with exophthalmic goiter had seemed definitely contraindicated.

The action of iodin in a case of exophthalmic goiter is not definitely known, but the following is supposed to be the basis: The syndrome of adenomatous goiter with hyperthyroidism is the result of an excessive amount of thyroxin in the tissues, and it can be produced experimentally by the feeding of excessive amounts of thyroid extract or thyroxin to myxedematous patients. In short, adenomatous goiter with hyperthyroidism is pure hyperthyroidism.

In exophthalmic goiter there is the same syndrome with certain additional characteristic symptoms, such as exophthalmos, nervous and gastro-intestinal phenomena, and a tendency toward spontaneous crises. The cause of exophthalmic goiter is not known. Plummer suggests, as an explanation of the development of the characteristic features, that intensive stimulation of unknown source, acting on the entire gland, drives it to the point of producing an active agent, abnormal in quality as well as quantity, which in the tissues of the body causes all the phenomena of the disease. As the normal molecule of thyroxin, discovered in 1914 by Kendall, contains 65 per cent. by weight of iodin, it was natural to speculate as to the possibility of an incompletely iodized molecule, and Plummer conceived the theory that the syndrome of exophthalmic goiter varies with the total amount of a completely iodized molecule, and with the relative amount of the two molecules in the tissues. Iodin is therefore administered on the theory that it will completely iodize the molecule thyroxin.

At first the iodin was used only in selected cases, and administered continuously for short intervals in small doses of from 5 to 10 minims (0.3 to 0.6 c.c.) a day. In most instances clinical improvement and lowered basal metabolic rates were noted, and its value in the preoperative preparation of patients with exophthalmic goiter was early proved; then all patients with exophthalmic goiter were placed under this regimen. There remained the establishment of proper dosage. Occasionally, in the earlier experience, patients who had had iodin preoperatively had marked postoperative reactions, and from a study of these it was learned that the dosage had to be increased and administration prolonged to include not only the day of operation but the immediate convalescing period as well. For the last eighteen months or two years, there has been no noteworthy change in its administration. The dosage is adapted to the patient. The minimal dosage in the milder cases is 10 minims once or twice a day for five days; the average is 10 minims three times a day for from seven to ten days, and the maximal, for patients in a crisis or intensely stimulated on admission, from 60 to 100 minims (3.7 to 6 c.c.) daily until the crisis has subsided. After the crisis, 10 minims is given three times a day for from ten to twenty-one days or longer, depending on the severity of the case and the rapidity of the improvement.

The clinical effect of administering iodin to patients with exophthalmic goiter who are being prepared for operation has been striking. An early change is manifested by loss of conscious nervous tension and stare, and improvement in appetite and ability to sleep. In a few days to a week, the pulse and basal metabolic rates drop, often 30 or 40 points each, and shortly there is an appreciable gain in strength and weight. The improvement is not equal in all patients. In general, the more toxic the patient, that is, the more pronounced the cerebral stimulation and gastro-intestinal irritation, the more extraordinary is the improvement. In the milder cases the benefit is less apparent, and in a small group, with the hard, "trained" goiter of long duration, very little measurable improvement is noted on the administration of iodin. From a study of the course of the disease following ligation when large doses of iodin were administered continuously for long periods, Boothby[4] concluded that, after the marked initial improvement due to the iodin, the condition of the patient becomes relatively stable and no further improvement occurs. Repeated observations on the effect of the iodin administered continuously for a year or longer have confirmed this conclusion, so there is no rational basis for administering iodin in cases of exophthalmic goiter with the expectation of curing the disease.

The preoperative administration of iodin to patients with exophthalmic goiter has a definite and nearly constant effect on the pathologic picture of the thyroid gland. According to Broders, who has had the opportunity to study many hundreds of specimens, the histologic alterations are often diffuse and characterized chiefly by dilatation of the follicles, presenting a "Swiss cheese" effect, a change in the lining epithelium from columnar to cuboidal and even to flat cells, and an increased deposit and thinning of the colloid material.

---

[4] Boothby, W. M.: The Use of Iodin in Exophthalmic Goiter, Endocrinology **8**: 727-745 (Nov.) 1924; Iodin in the Prevention and Treatment of Goiter, J. Indiana M. A. **18**: 5-8, 1924.

This method of preoperative preparation has had a remarkable and gratifying influence on the results of the surgical treatment of exophthalmic goiter. This cannot be accounted for entirely by the apparent improvement in the condition of the patient or by the lowering of the metabolism, for in the past many patients died after a simple ligation, whose appraisable symptoms had a much better rating than those who now after treatment go through a subtotal thyroidectomy without any reaction.

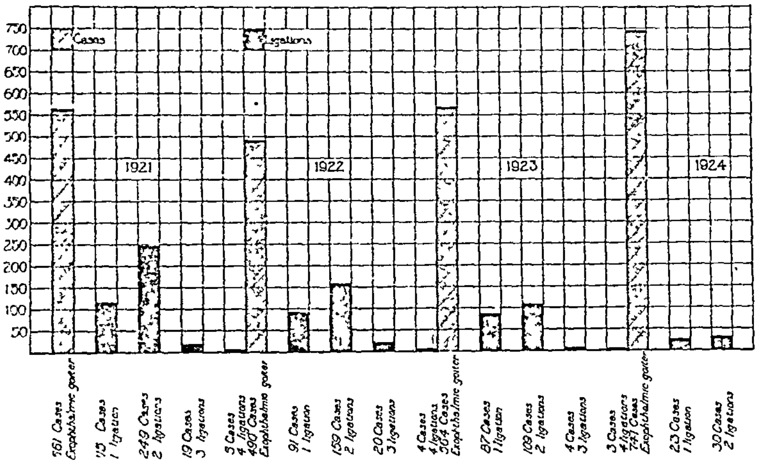

Chart 1.—Yearly cases and yearly ligations

There is a certain phase or status in the course of the disease which, when present, increases the liability to an explosive hyperthyroid reaction, induced often by a trivial stimulus, such as a minor operative procedure or even great excitement. In many instances this status is manifested by intense mental and nervous stimulation or depression and a tendency toward gastro-intestinal upsets, whereas in other instances there are no reliable indications of it, and its presence is not known until the development of the explosion. It is more often associated with high basal metabolism than with a relatively low metabolism. By proper preoperative preparation with iodin, this phase of the disease may be completely dissipated, thereby eliminating the postoperative hyperthyroid crises, so that today the operative treatment of patients with exophthalmic goiter is rid of its greatest hazard, that most feared complication which formerly was potentially ever present to rob the surgeon of the fruits of his labor. However, it should be recognized that in the surgical treatment of exophthalmic goiter there is, besides the danger of the acute postoperative reaction, another hazard, the debility of the patient incident to the acuteness of the disease, or the result of visceral damage. If the latter is marked, the amelioration of the symptoms of hyperthyroidism by iodin treatment will not immediately remove this hazard; therefore, sufficient time should be allowed for the restoration of the patient's strength and weight before major surgical measures are advised.

The degree or intensity of hyperthyroidism should not be the sole criterion on which to base the decision for operation; consideration of the patient's general condition is equally essential. Even if iodin is administered, ligation of the thyroid arteries and a two months' convalescent period may also be indicated in the management of the most severe cases. It is apparent, then, that cautious judgment must still be exercised as to the selection of the time and type of operation for the individual patient. When these precautions are not observed in the management of the greatly debilitated patient, the convalescence may be complicated by the development of pulmonary disorders, congestion, edema and pneumonia, or by infections, such as pericarditis, pleurisy and arthritis, or by general metabolic disturbances.

EFFECTS OF PREOPERATIVE PREPARATION WITH IODIN IN CASES OF EXOPHTHALMIC GOITER

The convalescent period has been materially shortened by the elimination of marked postoperative reaction, so that today the postoperative hospitalization period for patients with exophthalmic goiter is about equal to that of patients with adenomatous goiter without hyperthyroidism. There has been a steady and spectacular decrease in the number of multiple operations with increasing experience with this method[5] (Charts 1 and 2). The proportion of ligations performed at the clinic in 1924, to those performed in 1921, before the introduction of iodin treatment, was 1:11. It can be readily appreciated that the economic advantage to the patient effected by the reduction in the number of ligations has been tremendous. The operability of patients with exophthalmic goiter has been materially extended, as shown by an analysis of the records.

Every year at the Mayo Clinic there are a number of patients with exophthalmic goiter who are in a state of actual hyperthyroid crisis when they are examined, or who develop it shortly thereafter before operation. A certain proportion of these die before operation. The average yearly deaths of patients not operated on for the four years preceding the introduction of iodin was more than fourteen (Chart 3). In 1924, the proportion of these dangerously sick patients admitted was as great as in preceding years, but only two died, and the others improved so much after the treatment with iodin that they were soon accepted for operation, thereby materially extending the operability to a class of patients

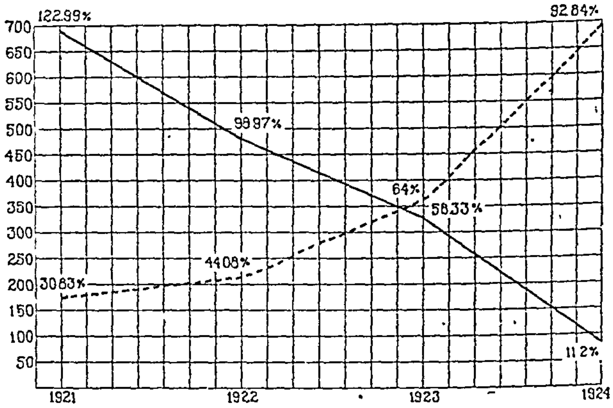

Chart 2.—Increase in percentages and numbers of primary thyroidectomies (broken line) and decrease in percentages and numbers of ligations (solid line).

---

[5] The use of iodin was begun in March, 1922.

who had previously died in a crisis on the medical service. Furthermore, of the patients who are allowed to go home for a period of rest after ligation, a certain number, for various reasons, do not return for the completion of the operation. Sufficient data are not available to classify these according to the causes for failure to return. My experience with patients who are temporarily very much benefited by the ligation is that there is a very high percentage of recrudescences. With the diminution in the number of ligations, the number of uncompleted operations in 1923 decreased to less than half (Chart 4). The data available for 1924 would indicate a further diminution in the number of uncompleted operations.

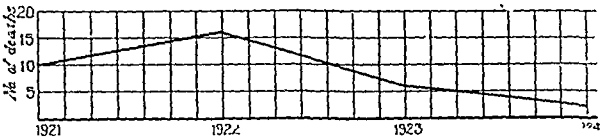

Chart 3.—Nonoperative deaths in cases of exophthalmic goiter from 1921 to 1924

The operative mortality has also been substantially lowered. Thus, for the year 1924 the rate was 0.6 per cent. by operation and 0.8 per cent. by case. It is notable that there were no deaths from preliminary surgical procedures, and furthermore, only one death resulted from an acute postoperative reaction. In this case the goiter was wrongly diagnosed as adenomatous goiter with hyperthyroidism, and no iodin given preoperatively.

ADENOMATOUS GOITER WITH HYPERTHYROIDISM

In order to reduce the mortality in cases of adenomatous goiter with hyperthyroidism, the management must be directed along entirely different lines. The patients in this group might be called the "procrastinating type"; that is, in most instances they do not seek medical relief until the disease has progressed so far that vital structures have been damaged, often beyond repair. We are all familiar with the patient who has had a nodular goiter for many years, but does not consider operation unless by chance the goiter causes choking or marked disfigurement. On an average of fifteen years after the appearance of the goiter, hyperthyroidism develops, but the onset of the symptoms is so mild and insidious that the patient often does not realize any change in his condition and hence does not seek surgical relief until evidence of visceral degeneration has developed, when the operative risk is high and the prospect of complete cure diminished.

Unlike exophthalmic goiter, the course of the disease is steadily progressive and, unfortunately, is not greatly influenced by any preparatory surgical or medical measures. Obviously, the operative mortality is in direct proportion to the number of bad risk cases accepted for operation. Therefore, the mode of attack to reduce the mortality and invalidism caused by this disease lies not so much in the further development of surgical technic or preparatory measures, as in the general education of the public. All nodular goiters should be removed soon after their onset, or the patients should be under periodic medical observation, so that the symptoms of hyperthyroidism may be detected early. As the successful removal of the adenomatous tissue results in the permanent disappearance of the hyperthyroidism within from ten to fourteen days, thereby lifting an extra load from the already disabled organism, the surgical treatment of practically all patients with hyperfunctioning adenomatous goiter, without undue regard to the operative hazard, is amply justified.

In the Mayo Clinic during the year 1924, 370 subtotal thyroidectomies were performed in 370 cases of adenomatous goiter with hyperthyroidism. Four patients died, a mortality of 1.08 per cent.

SUMMARY

In the Mayo Clinic, in 1924, there were 1,928 operations on 1,725 patients with goiter. Ten patients died, a mortality by operation of 0.51 per cent. and by case of 0.58 per cent. There were 677 patients with goiter unassociated with hyperthyroidism, with no deaths; 368 patients with hyperfunctioning adenomatous goiter, with four deaths (1.08 per cent.), and 741 patients with exophthalmic goiter, with six deaths (0.8 per cent).

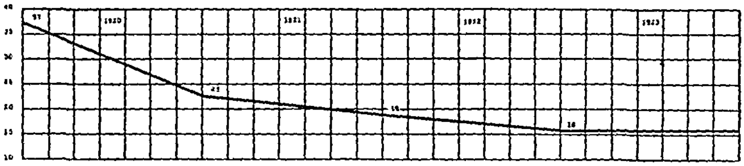

Chart 4.—Number of patients on whom ligation was performed and who did not return for thyroidectomy

This extremely low mortality rate achieved by present-day surgical treatment of the thyroid gland was made possible by the perfection of operative technic and the discovery of means of controlling hyperthyroid crises. The employment of the multiple-stage operation in selected cases, and refinements in management designed for the protection of the patient resulted in a tremendous reduction in the operative mortality and served to establish firmly the surgical treatment of exophthalmic goiter. However, on account of the failure to eliminate the hyperthyroid crises completely, and because of the obvious objections to the multiple-stage operation, this method left much to be desired. The proper administration of iodin to patients with exophthalmic goiter has completely controlled both the spontaneous and the postoperative hyperthyroid crises.

The influence of iodin on the surgical treatment of exophthalmic goiter is shown by the following clearly proved facts: 1. The convalescent period has been definitely shortened. 2. The necessity for multiple operations has been greatly decreased. 3. The limits of operability have been widened. 4. The mortality has been further reduced.

The problem presented by the patient with hyperfunctioning adenomatous goiter is one of procrastination, and the hope of its solution lies in the education of the public to the fact that all nodular goiters are potentially dangerous and should be removed unless the patient is kept under periodic medical observation.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. ELSE AND PEMBERTON

Dr. Frank H. Lahey, Boston: During the last six months, we have been interested in our clinic in the iodin content of various types of glands and the effect of iodin feeding on the histologic picture. While the histologic picture shows the change of complete involution under thyroid feeding, it is a clinical fact that this picture does not go hand in hand with thyroid function. Time and again, the histologic picture indicates that the patient was not toxic, while in reality he is still toxic and can be cured finally only by subtotal thyroidectomy. It is the duty of all who deal with patients with disease of the thyroid firmly to impress on the public that iodin is not a method of cure in exophthalmic goiter, but a method of preparing patients for operation. We rarely see such patients today who have not been on iodin feeding, and this is at times confusing, particularly in borderline cases, which are difficult enough to diagnose in the first place and are made more difficult by the administration of iodin. Medical practitioners should be urged not to administer iodin to patients before sending them to the surgeon. They should be turned over to him for iodin administration, permitting him to note its effect, to observe the patient and his degree of toxicity before the iodin is administered, and to see borderline cases unchanged by iodin feeding. Up to within the last year I have been skeptical of the value of iodin, but I wish to acknowledge to Dr. Plummer a debt of gratitude for the popularization of this very valuable method in preparation for operation. In dealing with patients with severe thyroid disease, one must bear in mind that even though compound solution of iodin markedly improves them, treatment must still be administered cautiously. If one operates on a number of patients who have had this treatment at a certain stage, he will be surprised to find that every once in a while, in spite of an apparent improvement, one of them may die in an active toxic condition. I believe that no matter how much patients are apparently improved by the solution, it is essential that one have in mind the degree of toxicity previous to its administration, and if any doubt exists, the operation should be divided into two hemithyroidectomies. In the past we have been most ardent advocates of the multiple stage procedure, and we have now largely given it up because of the preliminary use of compound solution of iodin. So far this year we have done 380 thyroid operations on 358 patients, 116 of which have been cases of primary hyperthyroidism. Out of this number of cases of exophthalmic goiter, 100 were completed in one stage and sixteen in two stages by two subtotal thyroidectomies, and no preliminary ligations have been done this year. There has been one death from pneumonia out of the entire series this year. We still believe that, when the slightest doubt exists, a two stage procedure, being the one of caution, should always be employed, rather than to take the slightest chance with the one stage procedure.

Dr. B. T. King, Seattle: Dr. Else has again brought to our attention the question of nonencapsulated adenomatous tissue. I have the impression that the various pathologic descriptions that have been given by different men are not sufficiently uniform to create the impression that the respective writers are agreed on a clear and definite pathologic entity. Wilson of Rochester first described nonencapsulated adenomatous tissue. Later Goetsch described a condition that he termed diffuse adenomatosis. As I recall, he described a condition that he had frequently encountered in patients with a clinical history not greatly different from chronic tuberculosis. A number of his patients had actually been confined in sanatoriums for the treatment of tuberculosis. The pathologic picture he found was of more or less diffuse areas of epithelial cells scattered throughout the gland, with frequently no effort, or abortive effort at least, at acinae formation. The pathologic picture presented by Dr. Else does not appear to correspond with that picture. We have all seen glands similar to those described by Dr. Else. This type of gland is one that develops, as a rule, near puberty, persists as a large diffuse uniform enlargement of the gland for years, later becomes more or less nodular, and under conditions of age, child-bearing, etc., not infrequently grows toxic, presenting a symptomatology not unlike that observed in encapsulated toxic adenomas. These glands grossly are often large, with long bat wing-like projecting poles that extend high in the neck and often below the clavicles. I have been in the habit of classifying them as adenomas associated with colloid goiters, and in operating I have attempted to remove as much as possible of the glossy lobulated tissue that is grossly giving evidence of growth. With the present classification of goiters and the wide variety of pathologic pictures presented under the generally accepted headings, it is questionable whether a new classification will clarify a subject that at best is poorly understood. Only this morning, in the Section on Practice of Medicine, I heard exophthalmic goiter described as one phase of autonomic imbalance, which included everything from Raynaud's disease on one end to exophthalmic goiter on the other, not excepting allergies and pyloric stenosis. However, we can make progress only through new ideas, and it has been interesting to listen to Dr. Else's discussion. I am delighted to hear the excellent results which Dr. Pemberton has had. Also, I share equally with Dr. Lahey his enthusiasm for iodin in the treatment of exophthalmic goiter. Associated with the type of thyroid reactions Dr. Pemberton has mentioned, one encounters acidosis and, frequently, acetone in the urine. Acetone is an end-product of excessive fat and protein metabolism. In the past, surgeons have operated on these patients after they had fasted from twelve to eighteen hours, when the glycogen supply of the liver had been almost completely exhausted. The surgeon induces a hypermetabolism, which, in the absence of carbohydrates, results in acidosis and acetonuria. It has been demonstrated that compound solution of iodin reduces metabolism and postoperative reactions. To my mind it is more rational to prevent acidosis with this solution than to treat it with carbohydrates and alkalis.

Dr. E. P. Richardson, Boston: The introduction of the use of compound solution of iodin in the treatment of exophthalmic goiter marks a most important day, and I am glad to bear tribute to its progress. At the Massachusetts General Hospital for two years we have followed rather closely a small group of cases. We have found, as they have in other clinics, a marked remission in the course of the disease, ordinarily reaching a maximum in from eight to twelve days, an average drop of from 25 to 30 per cent. in the basal metabolic rate, marked clinical improvement and, particularly, marked lessening in the nervous tension. Compound solution of iodin has affected our clinic in two ways. In the first place, the percentage of immediate subtotal thyroidectomies is now over 80. In the second place, it has influenced us in regard to roentgen-ray treatment. Some years age we tried to judge clinically between the effect of roentgen-ray treatment and the effect of operation in exophthalmic goiter. The effect of operation was distinctly superior to the effect of the roentgen ray. Except in very unusual cases, the roentgen ray is not used in our clinic in the treatment of this disease. There are, however, some possibilities of harm in the indiscriminate use of iodin. In the first place, when it is used as a means of medical treatment, it has been shown that the effect is temporary and does not cure the disease. In the second place, as Dr. Lahey has said, it is difficult in some cases to make a diagnosis, and in these cases it is necessary to stop the iodin and wait some weeks before making a diagnosis. Another harm from the use of iodin is in adenomatous goiters, when it may bring on hyperthyroidism. As an aid to surgery, it is unwise to put too much stress on iodin. It improves these cases but does not make then normal operative risks. Even if postoperative crises do not occur, patients are apt to go through operation with a rapid pulse and great sensitiveness to operative trauma and complications; more so than normal persons. Much has been gained by the use of iodin, but it does not convert these patients into normal risks. Another possibility of harm is the sudden omission of iodin after partial thyroidectomy, whereupon there is a possibility of the development of a thyroid crisis. The use of iodin, therefore, is not a cardinal treatment or a medical treatment; it is part of surgical treatment, just as is preliminary operation. The cases need to be properly diagnosed. The iodin must be continued during the postoperative period and in many cases continued in small doses after discharge from the hospital. Finally, some of these cases remain poor risks even after the use of iodin.

Dr. Allen Graham, Cleveland: It is not clear to me from the presentation whether Dr. Else intends to explain all adenomatous goiters as being one entity or as two distinct entities. In the illustrations shown, fetal adenoma, as described by Wolfler (1881), is not clearly differentiated from the type of diffuse adenomatous goiter described by Goetsch and others. Dr. King thinks it is not well to introduce a new classification. There is certainly no objection to the introduction of an entity, new or old, supported by facts. Adenomatous changes that take place in the thyroid are of two distinct types; namely, fetal adenoma, as described by Wolfler, and diffuse adenomatous goiter, having no relation to fetal thyroid. Fetal adenoma indicates congenital goiter, while diffuse adenomatous goiter is a change that takes place in long standing goiters as a result of alternating periods of hyperplasia and involution. In the former there is a great incidence of malignant disease, whereas, up to the present time, we have no convincing example of carcinoma that can be ascribed solely to diffuse goiter. I am heartily in accord with all Dr. Pemberton has said. There is no doubt that the administration of compound solution of iodin is a great advance in the treatment of cases of exophthalmic goiter. Iodin given to such patients can do no possible harm so long as the thyroid is actively hyperplastic. Clinical evidence of hyperplasia is an enlarged soft gland, with thrill and bruit. The effect of iodin administration is evidenced by increasing consistency of the thyroid, disappearance of thrill and bruit, together with clinical improvement. The practical points to be learned by further experience are the amount of iodin to be given, the duration of the iodin treatment, and the time at which to do the primary thyroidectomy. Since July, 1924, we have not performed preliminary operations on any patient under our care. We have been using 10 drops of compound solution of iodin three times a day, observing the patient's general condition, the condition of the thyroid, the metabolic rate, pulse, temperature, etc. Patients have invariably improved satisfactorily, and primary subtotal thyroidectomy has been done in one to three weeks after admission.

Dr. George W. Crile, Cleveland: When David Marine, in 1911, showed that iodin would convert a colloid goiter into one safe for operation, he urged me to use iodin before operation and I did in a certain number of cases. Unfortunately, I used iodin in cases of adenomatous goiter and had bad results with some very sick patients. Therefore, I discontinued the use of iodin but continued the use of large doses of thyroid extract before and after operation and during early convalescence. I have now taken Plummer's idea and give iodin before operation, but only when the glands are hyperplastic. The results have been a definite improvement in the operability of these cases. It should be borne in mind that iodin may induce hyperthyroidism in cases of quiescent adenomatous goiter. Therefore, when we recommend iodin in the preparation of cases for operation, we ought just as strongly to urge that iodin be not given in cases of adenomatous goiter in adults. The use of iodin has not been the only factor at play in reducing our mortality rate. The omission of ether anesthesia, better teamwork, the better recognition of the patient's condition as a whole, all have played their part. By taking the utmost care in building up the water equilibrium, in protecting internal respiration, in the management of the operation itself, we have been able to lower the mortality rate even without iodin. We have had one series of 125 cases without a death without the use of iodin, but we did use thyroid extract. At the present time we use compound solution of iodin only in cases in which the gland is hyperplastic. We have now a series of 441 cases without a fatality. I am making a plea for two things: first, that we do not relax at all in our care of the patient as a whole and in our careful technic in the handling of the patient, and second, that we avoid the use of iodin in cases that might be converted into hyperthyroidism.

Dr. Emil Goetsch, Brooklyn: When iodin is used before operation for exophthalmic goiter, it works wonderfully well. I am in accord with practically everything that has been said by the previous speakers on this subject and would like to offer some additional data on the use of iodin. I have had enough experience to know that when iodin is improperly used or not used in the sense that Dr. Plummer has described, one will not obtain the results that have been claimed. When one gives iodin as a preliminary measure and then delays the operation, he will not again have as favorable a chance. That has been my experience in a number of cases. When a patient has been iodinized thoroughly and then has a relapse, I feel I cannot successfully resort to iodin again. It should be made known, particularly among physicians, that the indiscriminate and repeated use of iodin deprives the surgeon of the opportunity to give his patient the striking benefits of an initial preliminary iodin course. This treatment is the greatest check there is in controlling the very active case. Dr. Else was kind enough to refer to my paper of 1920 in which I described the condition to which I gave the name diffuse adenomatosis. The fact that this condition did exist was mentioned previously, although it was differently classified. I believe it is this group of diffuse adenomatosis that has caused a great deal of difficulty to pathologists because of the varying nomenclature. I became interested in this type because of a number of patients in this group who had had treatment for supposed tuberculosis. One was a nurse who had been to a sanatorium. She was suffering from the syndrome characteristic of diffuse adenomatosis. The metabolic rate was not increased. However, ablation of the gland proved successful. The adenomatous tissue in diffuse adenomatosis is not encapsulated. The entire thyroid is involved. Some of the sections Dr. Else showed were typical of the ones I described; others were not. I am not sure whether in his description he was not including two different kinds of pathologic changes. In diffuse adenomatosis, there is no encapsulation. Anything with a capsule around it is easily differentiated grossly from other thyroid enlargements. Adenomas are characterized by one's ability to recognize them. Furthermore, on palpation the nodules can be felt. One cannot palpate nodules in diffuse adenomatosis. He must interpret the condition from the patient's syndrome and verify it microscopically. Total resection is the treatment and in many cases improvement is remarkable.

Dr. J. Earl Else, Portland, Ore.: Dr. King referred to my paper as bringing out a new classification, but as Dr. Goetsch has said, the describing of a definite pathologic entity is not introducing a new classification. There are two definite distinct pathologic processes: one an adenoma, with a definite capsule, and the other a diffuse adenomatous goiter, with nodular-like masses that for the most part are not definitely encapsulated. Reference has been made to the use of iodin. Iodin has been shown to be of great value in the prevention of goiter. Plummer has demonstrated its value in preparing patients with toxic hyperplastic goiter for operation. But in the treatment of simple goiter we have had little success with its use. At the Goiter Clinic of the University of Oregon, we ran four series of cases of adolescent goiter. In the first series, we gave 10 mg. iodin a day. In the second series, we gave 1 grain (0.06 mg.) of sodium iodid three times a day. In the third series we gave sodium iodid in larger doses, and in the fourth series we gave desiccated thyroid. The patients were observed for a period of from six months to two years, during which time the majority reported every two weeks to have the pulse counted, the neck observed and such other observations made as were necessary. The results were uniformly poor in the series in which iodin was used regardless of the dosage. In the group receiving desiccated thyroid, the results were uniformly good. There were some that did not yield, but the vast majority responded in two or three months. After the thyroid returned to normal, the patients were put on the preventive iodin treatment.

Dr. John deJarnette Pemberton, Rochester, Minn.: This discussion has revolved about iodin. I want to emphasize a statement that was not sufficiently stressed in my paper. In the Mayo Clinic, iodin is given to patients with exophthalmic goiter only as a preparatory measure for surgery, and not with the idea of curing the disease. We believe that by the use of iodin the postoperative hyperthyroid reactions will be controlled completely. This does not mean that iodin will in itself restore the patient to health, because it will not, but by its administration over a certain period of time, the patient may be safely carried through operation. I think it can be prophesied with confidence that within a few years ligation will be the exceptional rather than the prevailing method of preparing the bad risk patients for operation.

RECURRENT TYPE I PNEUMONIA *

LAWRENCE A. KOHN, M.D.
ROCHESTER, N. Y.

The likelihood that a single attack of pneumonia may predispose to subsequent attacks has long been recognized. Statistical evidence has been presented which bears this out: thus, Norris[1] found that of 11,811 cases of pneumonia which he was able to collect from the literature, there had been a previous attack in 1,615, while Cole[2] obtained a history of previous pneumonia in 137 of 607 patients he observed with the disease. Direct observations of two attacks in the same person are relatively infrequently recorded but may be found (among recent reports those of Thomas[3] and Thompson[4] may be cited), and there are instances of many attacks. Cole saw three of the eighteen attacks which affected one individual and found Type III pneumococci in those observed. Norris cites a case of twenty-eight attacks, before the recognition of types of pneumococci. With the increasing knowledge of immunity in pneumococcus infections, it has been thought that Types I and II probably immunized against homologous reinfection. Experimentally, Cecil and Blake[5] found that an attack of Type I pneumonia in the monkey protected against reinoculation one month later. Cole, however, had one case in which Type I pneumonia recurred at an interval of eight months and Thomas observed a patient who, with a history of a previous untyped pneumonia, suffered two attacks due to Type I pneumococcus at an interval of thirty-one days, crisis and recovery both times following the administration of therapeutic serum. As other instances of this kind were not found in the literature, a case closely resembling that of Thomas is thought worthy of record.

REPORT OF CASE

W. S. T., a student, white, aged 20, entered the Peter Bent Brigham Hospital, Nov. 19, 1924, following an hemoptysis. One sister had died of pulmonary tuberculosis at the age of 12; otherwise the family history was unimportant. He was not habituated to alcohol. He had first had pneumonia at the age of 9, and four other attacks of varying severity, all in the spring of the year, followed before he was 15. In none of these was the sputum typed. There were no other data of importance in the past history save that one afternoon in the spring of 1924, while doing light work, he had coughed up blood. Roentgenograms of his chest at another hospital at that time had shown no definite evidence of disease, and after a three weeks' rest in bed, he resumed his normal life. For two months prior to admission, he thought he had tired more easily than before, but he had held his weight and had not coughed until ten days before admission. The morning of his admission, he coughed up about one-half glass of dark blood and promptly came to the hospital. He remained here four days. He had no elevation of temperature and no subsequent hemoptysis. Physical examination showed him to be well developed and well nourished. The teeth were dirty, with several partially filled cavities. Save for fine crackling râles heard by one observer on one occasion at the right apex, the lungs were clear. The examination was otherwise negative. The clinical pathology was normal, and he raised no sputum that could be examined. The lungs were clear by roentgen ray. He was discharged November 24, with a diagnosis of hemoptysis, cause unknown.

He was readmitted, March 21, 1925, complaining of fever and weakness. In the interval, he had felt well and had attended school. He had had one cold in late December, but no hemoptysis or chronic cough, and his weight had remained the same. The night of March 19, following exposure to a draft, he had developed sensations of warmth, sweating, headache and shivering. In the morning he had an unproductive cough and pain in the right chest. A physician sent him to the hospital. He was only moderately ill, with a temperature of 104, pulse from 100 to 120 and respirations 25 per minute. There was moderate dyspnea. His cheeks were flushed, with circumoral pallor and slight cyanosis of the lips but no herpes. Respirations were shallow, rapid and chiefly abdominal; there was dulness at the right lung base behind, with tubular breathing, pectoriloquy and scattered râles. The hemoglobin was 92 per cent. (Dare instrument); the red cells, 5,700,000; the white cells, 15,000 in number, of which 87 per cent. were polymorphonuclear neutrophils. Blood culture, March 21, was positive for Type I pneumococcus, with less than one organism per cubic centimeter. The sputum was at first scanty; on the 24th, when first raised in sufficient quantity, it showed Type I precipitinogen and Type I organisms by the mouse test. No tubercle bacilli were found. On the 23d, after the blood culture was typed, treatment was begun with Type I pneumococcus antibody solution (Felton[6]), and a total of 160 c.c. was given intravenously in nine doses. On the 25th, his temperature fell by crisis, and he had an uneventful convalescence without serum sickness. April 6, chest films showed a diffuse postpneumonic residue in the lower right lung. He was discharged, well, April 9.

He was admitted for the third time, May 2, 1925, complaining of pain in the left side. During the interval he had been well. April 29, he was slightly chilled while witnessing a baseball game. The night of April 30, while dining, he suddenly had severe left-sided thoracic pain, aggravated by inspiration and coughing and accompanied by dyspnea and headache but no chill. The following day, there was nausea and vomiting and one severe chill; his cough became more annoying and he began to raise brownish sputum. There was a sensation of fever. His physician sent him to the hospital. He was extremely ill, with a temperature of 103, pulse from 120 to 140, and respirations from 30 to 40 per minute. He was restless and dyspneic. There was malar flush but no herpes or cyanosis. Breathing was rapid and shallow. In the left axilla and at the left base posteriorly there was dulness, tubular breathing, increased voice sounds and a questionable friction rub, but no râles. There were a few moist râles at the right base. The pulse was regular but small in volume. The examination was otherwise negative. The hemoglobin was 72 per cent.; the red cells 4,510,000, and the white cells, 9,800, of which 86 per cent. were polymorphonuclear neutrophils. Subsequently, the white count rose to 20,000, May 5, and then declined. There were rare urinary casts throughout the febrile period. Blood culture, taken May 2, gave no growth. Sputum was not raised till May 4; it was blood-tinged, was negative for tubercle bacilli and showed Type I pneumococci on mouse inoculation. A roentgenogram of the chest, May 2, showed large areas of increased density at the periphery of the left lung and at the central portion and upper lobe of the right lung. The roentgen-ray interpretation was bronchopneumonia. His condition became worse, with an average temperature of 104, marked lividity and dyspnea and tracheal râles. He was irrational and was twice out of bed. Caffein, strychnin and digitalis were administered, and on the 5th, when the type of infection was established, treatment was begun with Type I antibody solution (Felton), of which he received 75 c.c. in five intravenous injections. Crisis began that night, the temperature falling to 99 the morning of the 6th, with a corresponding drop in the pulse, slowing of the respiratory rate and marked general improvement. His convalescence was uneventful, undisturbed by serum sickness, and he was discharged, well, May 27. He has been observed almost weekly since that time and appears in excellent health. A roentgenogram of his chest in July, two months after discharge, showed some residual increase in hilar markings but excellent clearing. He has been receiving weekly injections of polyvalent pneumococcus vaccine in the hope of averting further attacks.

COMMENT

The first attack recorded was undoubtedly a lobar infection, and the isolation of pneumococci from the blood stream with the presence of organisms and abundant precipitinogen in the sputum establishes it as due to Type I. The second attack, while involving three separate lung areas in three lobes, was nevertheless croupous pneumonia, clinically, and the patches of consolidation appeared by the roentgen ray to be larger than those usually involved in lobular pneumonia. The sputum was twice injected into mice, and each time a pure culture of pneumococcus Type I was recovered. This organism was fatal to mice when injected intraperitoneally in quantities down to 10^{-5} c.c. of eighteen hour broth culture, and was agglutinated to the titer of Type I agglutinating serum (1:64). It is exceedingly unlikely that any other organism was responsible for the pneumonia.

As a rule, antibodies to the pneumococcus are found during convalescence from Type I pneumonia: protective substances (Dochez,[7] Baldwin and Rhoades[8]), agglutinins (Chickering,[9] Blake[10]) and opsonins (Clough[11]) are present in the serum of many patients. The administration of preformed antibody during the illness makes tests for these substances of little value. It may be noted, however, that on March 3, at the height of the first attack and before the administration of antibody solution, the blood serum of this patient protected mice in the approximate proportion of 1 c.c. against 100 fatal doses of Type I pneumococci, whereas at a similar time in the second attack the proportion was 1 c.c. against from 5 to 10, and one month after discharge from the second attack, against ten fatal doses. After two months of subcutaneous immunization with a polyvalent vaccine containing an excess of Type I organisms, the titer was again 100 units to the cubic centimeter. What this might imply, in relation to a possible peculiar inability on the part of this patient to elaborate antibodies, would involve unjustified speculation. It is well to add that, though cultures of the nose and throat two weeks after the second attack failed to show Type I pneumococci, swabbings from the pharynx, Aug. 17, 1925, showed numerous colonies of this organism. Unfortunately, the virulence was not determined. It is possible that the patient is a carrier who occasionally succumbs to the organism present in his pharynx.

SUMMARY

Two attacks of Type I pneumococcus pneumonia occurred at an interval of six weeks in a person who had suffered from several previous untyped pneumonias. There was little response in the production of humoral antibodies to these attacks.

Strong Memorial Hospital.

Clinical Notes, Suggestions and New Instruments

REVERSE PERISTALSIS ASSOCIATED WITH NAUSEA

JOHN H. FITZGIBBON, M.D., PORTLAND, ORE.

Recent contributions by Alvarez[1] and Keeton[2] have presented interesting and valuable evidence as to the cause of nausea. Both find the bowel to be an important factor in nausea production. For a number of years, Alvarez has considered it "very probable that it is brought about by reverse peristalsis, particularly in the bowel."[3]

Clinical evidence has not been abundant, because of evident difficulties in human experimentation. A case recently observed, however, demonstrates very definitely the association of reverse peristalsis and nausea.

REPORT OF CASE

Mrs. E. M., aged 61, referred to me by Dr. H. M. Greene, July 27, 1925, gave a history of intermittent abdominal distress for several months up until two years ago. A diagnosis of peptic ulcer was made by the family physician. After treatment, she was comfortable until three weeks before I saw her, when pain in the epigastrium reappeared. At times, it came on from thirty minutes to one hour after meals, and was relieved by food. The patient frequently was awakened at midnight by distress and by regurgitation of the gastric contents. Nausea was marked when pain was present, but she usually kept from vomiting.

A physical examination gave negative findings, except for tenderness along the colon and in the epigastrium. The Wassermann examination was negative. Three specimens of vomitus showed free hydrochloric acid, 60; total acidity, 83, and occult blood, strongly positive. The urine was normal; the stools contained a large amount of occult blood in five specimens.

Fluoroscopy revealed a constant defect of the lesser curvature, about 1 inch from the pylorus. Vigorous peristaltic waves were seen, but, at times, reverse waves took their place and passed completely and forcibly from the pylorus to the cardia. If, however, a downward wave was met, both faded out. At one time barium had just entered the duodenum, when reverse waves began, and it was seen to pass backward to the pylorus with a sudden rush. It was not possible to tell whether or not some of it entered the stomach from the duodenum.

Whenever reverse waves began, the patient experienced nausea; when the waves were vigorous, vomiting was prevented with difficulty. As the waves subsided, nausea disappeared and normal peristalsis was resumed for a short time, followed by another period of reverse waves and nausea.

An operation, performed by Dr. Rockey, revealed an indurated ulcer, of questionable appearance, involving the lesser curvature and posterior wall. Pyloric resection was done, and microscopic examination confirmed the suspicion of malignancy.

COMMENT

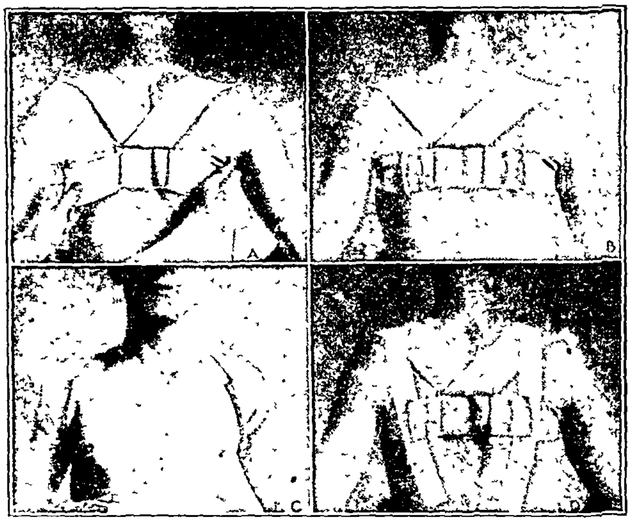
In this case, definite reverse waves of the stomach and of the duodenum were seen. Nausea accompanied the reverse peristalsis and seemed to vary with the force of the waves. Because of the rapidity with which barium passes through the duodenum, it was difficult to see reverse waves in that organ, except in one instance, when barium was rapidly forced backward along the duodenum to the pylorus.

Stevens Building.

A SIMPLE APPLIANCE FOR FRACTURED CLAVICLE

S. H. Rynkiewicz, M.D., Kingston, Pa.
Roentgenologist, Nesbitt West Side Hospital

A simple appliance for effecting and maintaining retraction of the shoulders in fracture of the clavicle consists of a strip of 2½ inch cotton webbing, 58 inches long, and a wire square (as at *A* in the illustration). The child size is a strip 2 inches wide and approximately 40 inches long, with a correspondingly smaller square. The square is made from No. 10 rust-proof clothes-line wire and is bent in a vise into a rectangle form, 2½ inches by 3 inches for adult size, and 2 inches by 2½ inches for child size. The ends of the wire are welded or may be bent in link form to lock.



An appliance for fractured clavicle: *A*, retraction of shoulders accomplished by making traction on the ends of the cotton webbing strip; *B*, each end fastened by strong safety pin; *C*, front view, with felt pads in position; *D*, strip of adhesive over each shoulder holding appliance in position.

The method of accomplishing as much retraction of the shoulders as is necessary simply by making traction on the ends of the cotton webbing strip is indicated in *A* of the accompanying figure. *B* shows each end fastened by a strong safety pin. The front view, with the felt pads in position, is seen in *C*. The pads are so applied that there is no danger of injury to nerves or blood vessels. *D* shows a strip of adhesive, extending from the lower part of the chest posteriorly over each shoulder to the upper part of the chest anteriorly. This adhesive firmly holds the appliance in position. The adhesive strip on the affected side may, if necessary, include a pressure gauze pad over the clavicle fragment.

A wedge-shaped pad under the shoulder of the affected side held in position by two or three turns of a 3 inch muslin bandage, forming a figure of eight, up, over and under the normal shoulder contributes to better alinement of the clavicle and also to immobilization.

The appliance takes up very little space in the hand-bag or may be carried in a coat pocket. There is no fitting to be done and nothing to interfere with the roentgen ray. It holds the shoulders back with minimum discomfort.

Special Article

TYPHOID IN CERTAIN LARGE CITIES OF EUROPE IN 1924*

For comparison with The Journal's annual survey of typhoid mortality in the large cities of the United States and for its general interest, The Journal presents a survey of typhoid in certain large European cities that have populations exceeding 100,000. The cities are grouped by countries.

A remarkably low typhoid death rate prevails in the large cities of Great Britain (Table 1). Probably no other country in the world can show so long a list of large cities free from a single typhoid death. No fewer than fifteen cities in Great Britain with a total population of 2,256,700 have a perfectly clear record for 1924, not a single typhoid death occurring in the whole of this large urban population. In the total list of fifteen British cities no municipality had a rate over 5 in 1924, and all but three had a rate less than 2.

Table 1.—*Death Rates of Cities in Great Britain from Typhoid per Hundred Thousand Population, 1924*

Brighton	0.0	South Shields	0.7
Cardiff	0.0	Woolwich	0.7
Coventry	0.0	Bristol	0.8
Derby	0.0	Liverpool	0.8
East Ham	0.0	Preston	0.8
Gateshead	0.0	Salford	0.8
Leyton	0.0	Greenwich	0.9
Middlesborough	0.0	Plymouth	0.9
Norwich	0.0	Bradford	1.0
Nottingham	0.0	Croydon	1.0
Rhondda	0.0	Hull	1.0
Southend	0.0	Newcastle-on-Tyne	1.0
Swansea	0.0	Lewisham (Catford)	1.1
Walthamstow	0.0	London	1.1
Wolverhampton	0.0	Stoke-on-Trent	1.1
Edinburgh	0.2	Leeds	1.2
Glasgow	0.4	Stockport	1.5
Leicester	0.4	Portsmouth	1.6
Birmingham	0.5	Manchester	1.8
Aberdeen	0.6	St. Helen's	1.8
Dundee	0.6	Sheffield	1.9
Sunderland	0.6	Southampton	4.2
Tottenham	0.6	Huddersfield	4.5
Willesden	0.6	Burnley	4.7

In other words, using the same criteria as adopted in our American survey, forty-five cities in Great Britain would be on the honor roll (from 0.0 to 2.0), three in the first rank (from 2.0 to 5.0), and none in the second or third rank. The largest city in the world, London, reports a typhoid rate for 1924 of only 1.1. Only seven American cities had a better record than this in 1924.

---

* The data contained in this article have been obtained in each instance from the municipal health officers. Death rates are figured on reported midyear population when this information could be secured; otherwise on the best estimate available. Owing to annexation of contiguous territory and other factors, the population of certain cities for 1924 is not in all cases comparable with that reported for preceding years, so that comparisons of these figures with earlier typhoid death rates is perhaps not warranted. As will appear in the lists of cities, we have not this year been able to obtain returns from all localities, since our requests or the answers to them have apparently miscarried.

In Germany (Table 2) the typhoid showing, although very good judged by most standards, does not reach the high degree of excellence shown in British cities.

TABLE 2.—*Death Rates of Cities in Germany from Typhoid per Hundred Thousand of Population, 1924*

Chemnitz	0.0	Hamborn-on-the Rhine	2.2
Karlsruhe	0.0	Elberfeld	2.5
Düsseldorf	0.2	Hanover	2.5
Krefeld	0.8	Duisburg	2.6
Gelsenkirchen	0.8	Cologne	2.6
Plauen	0.9	Mainz	2.9
Berlin	1.0	Augsburg	3.1
Frankfort-on-the Main	1.0	Essen	3.1
Nuremberg	1.0	Magdeburg	3.3
Leipzig	1.1	Barmen	3.7
Breslau	1.2	Cassel	4.1
Aachen	1.3	Stettin	4.1
Dresden	1.3	Mannheim	5.2
Munich	1.3	Altona	5.4
Hamburg	1.8	Lubeck	5.7
Saarbrücken	1.8	Brunswick	6.4
Münster in Westphalia	1.9	Bochum	7.0
Stuttgart	1.9	Halle	7.7
Bremen	2.2		

Only two of the thirty-six cities report no typhoid deaths, and more than half of the German cities have rates over 2. Six have rates over 5. On the whole, the typhoid rates in German cities in 1924 did not range notably lower than those in the large cities of the United States that have similar climatic conditions.

TABLE 3.—*Death Rates of Cities in France from Typhoid per Hundred Thousand of Population, 1924*

Strasbourg	0.6	Le Havre	6.1
Rheims	2.0	St. Etienne	6.5
Roubaix	2.6	Nancy	6.7
Lyons	3.0	Nantes	7.1
Rouen	3.2	Bordeaux	7.8
Toulouse	3.4	Brest	13.4
Lille	4.5	Marseilles	31.0
Paris	5.1		

Typhoid rates in the French cities (Table 3) are somewhat higher on the average than those in either Germany or Great Britain. So far as statistics are available, typhoid has for years been more prevalent in France than in Great Britain, Germany or the United States. In general, the northern French cities have lower rates than those farther south, the extremes being represented by Strasbourg (0.6) and Marseilles (31.0).

TABLE 4.—*Death Rates of European Cities Outside of Great Britain, Germany and France, from Typhoid per Hundred Thousand Population, 1924*

Stockholm, Sweden	0.0	Lwow, Poland	8.7
Zurich, Switzerland	0.0	Liége, Belgium	9.5
The Hague, Holland	0.2	Graz, Austria	11.1
Oslo, Norway	0.4	Riga, Latvia	11.2
Utrecht, Holland	0.7	Odessa, Russia	11.4
Copenhagtn, Denmark	1.0	Moscow, Russia	12.0
Helsingfors, Finland	1.0	Yaroslav, Russia	14.0
Antwerp, Belgium	1.3	Leningrad, Russia	14.6
Geneva, Switzerland	1.6	Vilna, Poland	15.0
Basle, Switzerland	2.1	Budapest, Hungary	15.5
Brussels, Belgium	2.3	Cartagena, Spain	15.8
Prague, Czechoslovakia	2.3	Oporto, Portugal	15.8
Dublin, Irish Free State	2.4	Athens, Greece	18.4
Danzig, Danzig	2.7	Warsaw, Poland	20.0
Vienna, Austria	3.7	Lisbon, Portugal	20.7
Bucharest, Roumania	4.1	Murcia, Spain	22.5
Amsterdam, Holland	4.2	Rome, Italy	26.2
Gottenborg, Sweden	7.4	Ufa, Russia	26.4
Ghent, Belgium	8.0	Lorca, Spain	40.0

In the rest of Europe (Table 4) there is a general, although not exact, correspondence between the latitude of the city and the typhoid rate, the cities in southern Europe averaging on the whole higher than those in the north. The Russian and Polish cities, however, appear to suffer more from typhoid than other European communities in the same latitude.

It should be noted that in many parts of Europe the 1924 typhoid rate was notably higher than that for 1923, the increase being particularly marked in the Baltic regions.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

OVARIAN SUBSTANCE, DESICCATED-P. D. & CO.—The entire fresh ovaries (including the corpora lutea) of the hog or cow, dried in vacuo and powdered.

Actions and Uses.—See Ovary, New and Nonofficial Remedies, 1925, p. 251.

Dosage.—Usually 0.3 Gm. (5 grains) daily.

Manufactured by Parke, Davis & Company, Detroit. No U. S. patent or trademark.

Tablets Ovarian Substance, Desiccated-P. D. & Co., 5 grains.

Ovarian substance, desiccated-P. D. & Co., is a yellowish or brownish powder, having a characteristic odor. It is partially soluble in water.

One part of the desiccated powder represents about six parts of the fresh gland.

OVARIAN RESIDUE, DESICCATED-P. D. & CO.—The residue from the fresh ovaries of the hog or cow, after removal of the corpora lutea, dried and powdered.

Actions and Uses.—Ovarian residue is used for the same conditions as those in which the entire ovarian substance is used. (See Ovary, New and Nonofficial Remedies, 1925, p. 251).

Dosage.—From 0.3 to 1.2 Gm. (5 to 20 grains) daily.

Manufactured by Parke, Davis & Company, Detroit. No U. S. patent or trademark.

Capsules Ovarian Residue, Desiccated-P. D. & Co., 5 grains.
Tablets Ovarian Residue, Desiccated-P. D. & Co., 5 grains.

Ovarian residue, desiccated-P. D. & Co., is a yellowish or brownish powder, having a characteristic odor. It is partially soluble in water.

One part of the desiccated powder represents about six parts of the fresh gland.

INSULIN-MULFORD (See THE JOURNAL, June 20, 1925, p. 1917).

The following dosage forms have been accepted:

Insulin-Mulford, 10 Units, 10 Cc.: Each cubic centimeter contains 10 units.

Insulin-Mulford, 20 Units, 10 Cc.: Each cubic centimeter contains 20 units.

Insulin-Mulford, 40 Units, 10 Cc.: Each cubic centimeter contains 40 units.

Insulin-Mulford, 80 Units, 10 Cc.. Each cubic centimeter contains 80 units.

DEXTROSE.—For description, see the U. S. Pharmacopeia X under Dextrosum.

The following dosage form has been accepted:

Ampoules Dextrose 50%, 20 Cc.: Each ampule contains 20 Cc. of a 50 per cent. solution of dextrose U. S. P.

Prepared by Swan-Myers Company, Indianapolis.

Dementia Praecox.—The fundamental clinical disorders of dementia praecox are a weakening of judgment, of attention, of mental activity and of creative ability, the dulling of emotional interest and the loss of energy. Lastly there is the loosening of the inner unity of the psychic life.—Sir Frederick W. Mott.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street - - - Chicago, Ill.

Cable Address - - - - "Medic, Chicago"

Subscription price - - - - - - Five dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new, always state whether the change is temporary or permanent. Such notice should mention all journals received from this office Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, DECEMBER 12, 1925

TO ALL FELLOWS AND JOURNAL SUBSCRIBERS

The small colored slip between these pages is a statement for 1926 Fellowship dues and subscription to The Journal. If enclosed in an individually addressed envelop and sent under two cents postage, the slip might seem more elegant, but it could not be more expressive. Those who have already paid will naturally disregard the slip. All others are urged to cooperate by remitting now and making it unnecessary to send special statements later.

The slip carries also the names and subscription prices of the various other journals published by the Association. Renewals or new subscriptions to any of these may be entered in the blank lines on the slip, and payment made with Fellowship and subscription to The Journal.

Special attention is also called to the color pages at the front of The Journal. In the past, many physicians have found that a subscription to one of the American Medical Association's special journals is an excellent holiday gift to a colleague. Then, too, many members of the profession will doubtless welcome the suggestion of gift subscriptions to *Hygeia*, the health magazine published by the Association. Special rates are offered at this time, and the gift order forms attached to the color pages can conveniently be returned with the statement for Fellowship and subscription dues. One remittance may be made to cover all dues and subscriptions.

IMMUNOLOGIC EVIDENCE AS TO THE EVOLUTIONARY RELATIONSHIPS OF MAN

In these days, when anything pertaining to evolution and the species relationships of man has news interest, much attention will probably be paid to a series of articles by *Landsteiner and Miller*[1] *of the Rockefeller* Institute on the serologic relationships of the blood of the primates. This topic aroused interest in the early days of immunologic investigation, when the blood relationships of different species, as shown by the new methods, were found to throw much light on the problems of biologic relationship and evolution. Nuttall's famous monograph on blood immunity and blood relationship, published in 1904, brought out the fact that precipitin tests with blood serum from primates showed a close relationship between man and the orang-utan, chimpanzee and gorilla, but less relationship between man and the monkeys. Other investigators obtained similar results and indicated that it was difficult to distinguish between human serum and that of the anthropoids by immunologic tests, but that there are readily discernible quantitative differences between human or anthropoid serum and the serum of the monkeys. Landsteiner, having found that species differentiation is more distinct between corpuscles than between the serum of different animals, has applied this fact to an investigation of the relationships of the corpuscles in the different available primates, studying the effects of agglutinins on corpuscles, and refining the results by determining the effect of removal of nonspecific agglutinins by saturation.

While these and other refined methods fail to differentiate the blood of white men and of American negroes, they do show differences between the corpuscles of human and of anthropoid blood, and between the corpuscles of two genera of monkeys, although the precipitin reaction as ordinarily employed fails to make these distinctions. But it is also clearly shown that the difference between the blood of the lower monkeys and the blood of the anthropoids or of man is much greater than that between the blood of man and that of the anthropoids. Indeed, according to immunologic tests, there seems to be less difference between the blood of man and that of the chimpanzee than between the blood of horses and that of donkeys, which species are so closely related that they can hybridize. This observation agrees with the interesting relationship that has been shown in the metabolism of these species; namely, that while nearly all mammals convert most of the uric acid arising in their metabolism into allantoin, man and the anthropoids differ from other mammals, including the common monkeys, in being unable to do this,[2] because man and the anthropoids alike lack the necessary uricolytic enzyme in their livers.[3] These demonstrations of biochemical relationships are in complete agreement with the view commonly accepted by zoologists that man is not evolved directly from any of the existing species of apes and monkeys, which laymen and the fundamentalists continue to assert is the doctrine of evolution, but the monkeys, the anthropoid apes and man have all merely sprung from a common stock, probably at some remote time. The serologic evidence does not indicate that anthropoids are an intermediate step between lower monkeys and man, for man and the anthropoids seem to be equally removed from the monkeys.

[3] Wells and Caldwell: J. Biol Chem **18**: 157, 1914.

Study of the natural agglutinins present in the blood of man and of apes shows that the anthropoid blood contains the same four groupings that are familiar in human blood, but that similar iso-agglutinogens are not present in the lower monkeys or in other mammals. To explain this fact, the simplest assumption seems to be that the iso-agglutinable factors existed before man and the anthropoids were differentiated from their common ancestor. Paleontologic studies have led to the generally accepted conclusion that the existing species of man is only one of a number of human species, the rest of which have become extinct, as for instance the Neanderthal man. If the group factors evolved before the human stage had been reached, they must have been present in these various fossil human species. At any event, we now find them present in man, the chimpanzee, the orang-utan, and presumably in the gorilla, which is not at present a laboratory animal, but not at all in the ordinary monkeys.

THE NERVOUS CONTROL OF INSULIN SECRETION

The assumption that the metabolism of sugar in the body may be regulated in some way through intermediation of the nervous system is by no means recent, for it originated with the classic piqûre or "sugar puncture" experiment of Claude Bernard in 1855. That investigation fortified the belief that stimulation of sensory nerves or lesions of the central nervous system may produce glycosuria. In the earlier studies of this "nervous diabetes," the implications were that somehow glycogenolysis was brought about by the changes initiated. It was assumed, for example, that there was a direct nervous stimulation of the hepatic cells leading to the augmented production of sugar from the glycogen stored there. Somewhat later, the popular explanation pointed to liberation of epinephrin, a sugar-mobilizing hormone, so that the hypoglycemic effects of nervous origin appeared to be exercised through the intermediation of the suprarenal glands.

The recognition of pancreatic diabetes as a disease entity and the introduction of the idea of insulin deficiency as a cause of sugar surplus have turned the trend of investigation. Whether we conceive of the pancreatic hormone as promoting glycogenolysis or glycolysis or both is of secondary moment in discussing the mechanism whereby the corrective insulin is liberated from the pancreas. Are nerves involved? So far as the external secretion of pancreatic juice is concerned, it has not been easy to demonstrate participation of either splanchnic or vagus nerves, although there is some evidence of the existence of secretory fibers running chiefly in the vagi. There is little doubt any longer that the islets of Langerhans are bountifully supplied with nerve fibers, particularly from the vagi.[1] Britton has remarked that such a wealth of neural elements, intimately related to the islet cells of the pancreas, is obviously of great significance and demands an explanation in terms of function. His own studies[2] at the laboratory of physiology in the Medical School of Harvard University furnish evidence that the internal secretion of the pancreas is affected by nervous influences, and that control of the secretion of insulin occurs through the right vagus nerve. Thus, under appropriate conditions, stimulation of this nerve upsets the constancy of the blood sugar level and produces a lowering of the blood sugar which persists during the period of stimulation. Blood sugar curves representing these results are similar to those obtained under insulin administration. When the stimulus is stopped, the original or even a higher glycemic level may be reached. These phenomena may happen without changes in the circulation; they are missed if the nerves and vessels of the pancreas are ligated.

The new experiments thus lend some support to the suggestion that disturbances of innervation also may be involved in the defective utilization of carbohydrates due to pancreatic disorder.

DEATH FROM ANOXEMIA

Nearly a century and a half has elapsed since Lavoisier drew attention to the true importance of oxygen. Since that time varying conceptions have been advanced with respect to the precise function of the element in the living organism. It was early held that the life processes are essentially those of oxidation, and the obvious analogies of the respiratory exchange with what takes place in ordinary combustion were naturally much stressed. However, there is no longer warrant for assuming that oxygen is the immediate cause of the chemical transformations in the body; it is rather the metabolism that determines the amount of oxygen to be absorbed. Respiration is not the cause of the instability of materials in the tissue cells; but rather the instability of reactivity in the cells is the stimulus for the active consumption of oxygen. Furthermore, the energy liberated in the organism, as in the contraction of a muscle, is not conceived at present to be the immediate outcome of an oxidative explosion but rather to have its source in other chemical changes. Oxygen "supplies the energy to recharge the energy reservoirs of the system."

Whatever the function of oxygen may be in ultimate analysis—whether, for example, it acts directly on the stored nutrients or only on such degradation products as lactic acid—in any event it is indispensable at some stage of the metabolic changes. The end-products of metabolism are almost without exception richer in oxygen—that is, more highly oxidized—than their precursors in the body. A recent writer[1] has remarked that oxidation is essential to the cell as the source of energy; energy is required for the internal and external work of the cell. By external work is meant the specific physiologic activity of the cell; in the case of the muscle cell, contraction; in the glandular cell, secretion, and in the nerve cell, the discharge of the impulse. By the internal work of the cell is meant that, in total absence of external work, the living cell requires energy for the maintenance of its structure, the directional work of permeable membranes, the maintenance of potential inequalities, and the prevention of free diffusion.

[2] Britton, S. W.: Studies on the Conditions of Activity in Endocrine Glands, XVII, The Nervous Control of Insulin Secretion, Am. J. Physiol. **74**:291 (Oct.) 1925.

Although the opportunity for securing oxygen in adequate amounts is rarely interfered with in the usual routine of everyday life, times of stress do arise. The element may be present but not available. "Oxygen," we are told, "like money, is of no value unless we can use it. Oxidation is the important thing for the cell, and oxygen want is but one of many means of reducing oxidation." What happens when an interference actually arises, when anoxemia intervenes? The appearance of organic acids in the urine and blood under such conditions long ago prompted the belief that acidosis, whatever that may have implied, is a prominent characteristic of oxygen deficiency. As a matter of fact, there may be an actual alkalosis of the blood in response to anoxemia. The phenomena have lately been clarified by the studies at the University of Wisconsin. The alkalosis observed is due to excessive loss during the accelerated breathing that occurs with oxygen want. This hyperpnea is, in turn, due to reduced oxidation in the cells of the respiratory center. After a certain period of time, according to the Wisconsin observations, the fixed acids produced as a result of decreased oxidation in the tissues of the body compensate for the loss of carbon dioxid, and the blood p_H becomes normal. Following this, there develops a most extreme grade of acidosis, depending on the degree and duration of reduced oxidation. According to the hypothesis, the acidotic type of metabolism induced interferes with oxygen fixation by the cell and thus further stimulates. This vicious circle of oxygen want and acidosis continues until oxidation is reduced to the point at which no functional activity can be supported. Then, we have depression or paralysis. Finally, the energy liberation is reduced to a point which does not even meet the small requirement of the internal needs of the cell. When the latter no longer is able to continue its usual functions, an irreversible change may ensue—death. Under such conditions, administration of alkali during the acidotic stage may actually prolong life.

Current Comment

THE POST-GRADUATE ASSOCIATION'S "MEDICAL TACTICS"

During the last few weeks the medical profession of this country has been widely circularized by a somewhat imposingly named concern, the "Post-Graduate Association," at 104 Hills Road, Cambridge, England. The advertising booklet sent out by the "Post-Graduate Association" is a red-covered affair entitled "The Management of Patients." The P. G. A. has for sale two "courses," one on "Medical Tactics," and another on Therapeutics. Either course alone is offered to American physicians for $5.50, or both courses for $10. Those who purchase the course on Tactics must sign a contract not to show it to any one else. While we have not seen the complete course, the syllabus, in the booklet already referred to, is intriguing. The course, it seems, instructs the physician how to so influence patients that they will come back again. It gives suggestions as to the doctor's house, its position, the character of its door and door plate, how the waiting and consulting rooms should be furnished, what instruments should be displayed—for psychic effect—and what instruments should be kept out of sight. It appears from the syllabus that the businesslike doctor must make sixteen impressions on each patient in an ordinary case—sixteen-to-one, 1925 model—and the P. G. A. course tells him how to make them. The single case in which it is judicious for the doctor to laugh at the patient is described. This alone should be worth five dollars. From the syllabus one gets the impression that this course in Tactics is similar in character and scope to the "course" of "lectures" given in American chiropractic factories on "How to Sell Chiropractic," except that in this instance it is applied to medicine instead of Palmerism. In order to lend an air of verisimilitude to an otherwise unconvincing narrative, the P. G. A. purports to quote "Press Opinions" of ancient vintage from some medical journals published in the British Isles. The leading opinion quoted is credited to the *British Medical Journal* of June 6, 1914. The quotations in this case are so staccato and so obviously separated from the context as to arouse suspicion. Reference to the *British Medical Journal's* original report shows that our British contemporary published a mildly ironical article that was not in any sense the favorable notice that the disjointed quotations lead one to suppose. Inquiry made in Great Britain brings the information that there is no Post-Graduate Association at Cambridge. The address given is that of the printing firm that got out the syllabus already referred to. So far as we can learn, the "Association" consists of a man (not a physician) and his wife who occupy a little office in the building of the printing establishment. It seems, too, that booklets similar to those circulated among American physicians have been distributed among British physicians, the only difference being that the Post-Graduate Association charges the Britishers six guineas (about $30) for what it offers to the American for $10. What do you make of that, Watson?

TYPHOID IN EUROPEAN CITIES

The survey of typhoid mortality in some of the chief European cities, presented in this issue,[1] makes possible a comparison of typhoid in American municipalities with the European prevalence of this disease. The remarkably low typhoid rates in British cities are especially striking. It is evident, however, that there is no longer the great discrepancy between American and European typhoid rates that existed twenty-five or even fifteen years ago. The large cities in Germany, for example, where the antityphoid campaign began early and was conducted with great skill and persistence, are now little if any superior in their rates to American cities. The survey also shows, although there are some cities unfortunately not on our lists, that typhoid is less prevalent, on the whole, in the northern cities than in the southern. This is precisely the same incidence observed in the geographic distribution of typhoid in the United States. Whether this is due to greater opportunities for transmission in cities with a mild or subtropical climate such as are furnished, for example, by more informal ways of living or by more ample opportunity for fly-borne infection, or whether there is a real climatic influence on susceptibility, are questions that can hardly be answered here. Quite possibly both factors may play a part. It will be of interest to observe in succeeding years whether the typhoid trend in Europe is as steadily downward as it has been in the United States since 1910. It can safely be predicted that the suffering and loss of life from typhoid throughout the world in the twentieth century will be only a fraction of what it was in the nineteenth.

RURAL VERSUS URBAN HEALTH

"It is usually those who spend much of their lives in the open who enjoy the best health and the greatest longevity. It is a great advantage to go into camp in the summer and to live in the country as much as possible. This is a fundamental requirement in any healthful living program."[2] These words from a popular exposition on how to live epitomize a widespread belief. By many the championship of the outdoor life is made synonymous with residence in the rural districts. Hence the city dweller has of late often evoked expressions of sympathy from those whom circumstance has protected from an urban existence. There are indications, however, that good health and fine physique are by no means an exclusive privilege of country folk; nor does the urbanite have a monopoly of all the infections and contagions. Not a little surprise was occasioned by the findings of Wood,[3] who concluded from the results of the examination of more than half a million school children that physical defects are greater in rural than in urban children. In harmony with this, Shepard and Diehl[4] ascertained, from an examination of students at a representative state university, that those who have been raised in villages and on farms show more physical defects and more multiple defects than those raised in large cities. The nature of the defects most frequent among students from villages suggest such possible common causes as neglect, congenital anomalies, poor development, frequent exposure to infection, poor hygiene and lack of school health supervision. At any rate, students raised in cities of more than 50,000 population show the lowest number of physical defects. These authors[5] have now supplemented their study by securing data on the relative occurrence of certain diseases previous to the university careers among groups of 5,000 students from various sized communities. Considering here the two extreme groups only, students from the rural communities are highest in past histories of pleurisy, pneumonia, rheumatism, smallpox and tuberculosis; they are lowest in respect to chickenpox, diphtheria, tonsillitis, typhoid fever and whooping cough. Students from cities of more than 50,000 population are lowest in past histories of appendicitis, influenza, measles, mumps, pleurisy and smallpox, but highest in the early incidence of chorea. Male students raised in villages give a history of having had the most diseases. The country and cities vie with one another, the record for low incidence of the common maladies being slightly in favor of the largest cities. It is unwise to dogmatize from statistics derived from a single region, Minnesota; but one cannot overlook the implied possibility that between the present-day rural and urban health-promoting activities the urban practices cannot be regarded as comparative failures.

A HUMORAL MECHANISM FOR GASTRIC SECRETION

The development of the hormone hypothesis in physiology has brought about a notable modification of the points of view from which various functions are now examined. Chemical substances, arising in various bodily localities, may pass into the blood stream and produce effects in distant organs. This provides for a chemical coordination of the activities of the organism working side by side, as Bayliss expressed it, with that through the nervous system. Function is no longer to be conceived of as stimulated or depressed through nervous impulses alone. There can be no doubt of the simultaneous efficacy of humoral regulations as well. The kidney transplanted from the abdomen to distant parts has been seen to preserve its secretory potency after all its nervous connections have been severed. The mammary glands likewise have been demonstrated to develop even after the integrity of their nerve supply has been destroyed. Now Ivy and Farrell[1] at the University of Chicago have given proof of the long postulated humoral mechanism for gastric secretion. They transplanted gastric pouches, severed from the stomach, into subcutaneous tissues in the region of the mammary gland, where the rich vascularity was likely to promote survival of the displaced parts. Such pouches secrete a gastric juice containing acid after a meal and after histamin and gastrin administered subcutaneously. This shows decisively that a humoral stimulus is one of the mechanisms concerned in the genesis of gastric secretion. Ivy and Farrell were successful also in stimulating the glands of the pouch by mechanically distending it with a balloon, which proves that a local mechanism is concerned, at least in part, in this type of stimulation. These new studies do not give a final answer to the question as to what occurs normally when the flow of gastric juice is incited. They merely enforce the admission of humoral possibilities in the domain of gastric secretion.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ARIZONA

Personal.—Dr. Kimball Bannister, Phoenix, recently won the state golf championship in a match at Clemenceau.

Society News.—The Yavapai County Medical Society met with the medical officers at Whipple, October 14, each group having in attendance 100 per cent. of its membership.——Dr. John C. Wilson, Los Angeles, addressed the Gila County Medical Society, Globe, November 3, on "Injuries of the Spine."

Hospital News.—At a recent meeting of the staff of the Arizona Deaconess Hospital, Phoenix, Dr. John W. Thomas was elected chairman of the staff; in the report of the chairman of the hospital for the last year, the total number of patients for the year 1924-1925 was said to be 1,817, which was an increase of 72 per cent. over the previous year.

COLORADO

Publicity Report.—The committee on public policy of the Colorado State Medical Society reported at the last annual meeting that in the year 1924-1925 there had been ten lectures and demonstrations in the series arranged for the public and that they cost about $1,600, of which the Colorado State Medical Society contributed about $250; the approximate attendance was 1,600. The subjects of the lectures were (1) The Miracle of the Roentgen Ray; (2) The Magic of the Microscope; (3) Vitamins; (4) The Man of 1940; (5) The Truth About Glands; (6) Teeth: Friends or Foes; (7) Cancer; (8) Medical Frauds; (9) The Dangerous Age; (10) Casting Out Devils.

Free Medical Service.—The visiting staff of the Denver General Hospital is composed of 125 physicians, appointed for one year for a period of service of from two to four months, during which they are subject to call day or night. *Municipal Facts*, published by the city and county of Denver, estimates that the hospital receives in service about a million dollars a year from these physicians. They say that this service is rendered cheerfully, that the visiting staff makes available to the poor the same medical advice that the rich receive and provides for emergencies for everybody and that however the city may improve the hospital, it is well to remember that Denver physicians bestow the gift inestimable.

CONNECTICUT

Personal.—Dr. Theodore S. Moise, Jr., has been promoted to an assistant professorship at Yale University School of Medicine, New Haven.

Further Assistance to General Practitioners.—Yale University School of Medicine, New Haven, has extended its cooperation with physicians of the state in arranging to have clinics conducted by members of the faculty at the Middlesex Hospital, Middletown. There will be a clinic each month covering pediatrics, surgery, medicine, obstetrics and gynecology, in charge of Drs. Edwards A. Park, Samuel C. Harvey, Francis G. Blake and Arthur H. Morse, respectively.

DELAWARE

Quack Grenoble Gets Two Years.—Sentences totaling two years were imposed, according to the Wilmington, Del., papers, on "Dr." Arthur G. Grenoble (alias Greenoble) on charges of embezzlement and practicing medicine without a license. He was sentenced to a year's imprisonment on each charge, the sentences to run consecutively. It seems that Grenoble borrowed money two years ago on the claim that he wanted to start a business of selling "Stommache Water." He did not start the business nor would he return the money; hence the charge of embezzlement. The other charge was lodged against him as a result of his treatment of an aged man for what was believed to be cancer. Grenoble has called himself "president" of a quackish outfit known as the "Grenoble Arthurg College," which purported to give a "postgraduate course in the treatment of cancer." Grenoble has been a notorious quack for years. In 1914 he was plying his trade in Key West, Fla., and carried full-page advertisements in the Key West *Morning Journal*. According to reports made at that time by the state board of health of Florida, the Monroe County Medical Society secured sufficient evidence against Grenoble (at that time he called himself "Greenoble") to get him convicted of violating the Medical Practice Act, but the quack had enough political and newspaper influence to be immune. He was twice convicted and sentenced in Florida. The first time a local senator and some other politicians succeeded in having his sentence revoked. On his second conviction he was fined $400, and a paper that carried his advertising came out with a two-column article deploring what it termed the outrage and abuse of justice in sentencing this "benefactor." A subscription was started by means of which enough funds were raised to pay Grenoble's fine. In 1921 Grenoble was quacking it in Atlanta, Ga., and in July of that year was sentenced to pay a fine of $500 and serve twelve months on the chain gang and three months in the county jail. The matter was reported at the time in this department of The Journal, Aug. 6, 1921. In 1923 Wilmington, Del., papers carried a news item to the effect that the Wilmington Preachers' Association had been impressed by Grenoble's assertion that he had discovered a cure for cancer and had named a committee to make an investigation.

DISTRICT OF COLUMBIA

Society Elections.—At the annual meeting of the Medical Society of the District of Columbia, December 2, at Washington, Dr. Joseph S. Wall was elected president; Drs. Charles S. White and Amelia Frances Foye, vice presidents; Dr. Coursen B. Conklin, secretary-treasurer, and Dr. William G. Morgan, delegate to the American Medical Association.——At the annual meeting of the Washington Tuberculosis Association, November 30, Dr. George M. Kober was reelected president and Dr. Harvey W. Wiley, vice president. Dr. William C. Gwynn and Dr. William C. White were elected members of the board of directors.

GEORGIA

Personal.—Dr. John O. Elrod, Forsyth, formerly president of the Medical Association of Georgia, has been appointed by the governor to fill the vacancy on the state board of medical examiners caused by the resignation of Dr. William C. Williams, Jr., Cochran.——Dr. Dunbar Roy has been elected professor emeritus of otorhinolaryngology at Emory University, Atlanta. Dr. Roy has been connected with the medical department of the school for thirty-one years.

ILLINOIS

Personal.—Dr. Thomas G. McLin, formerly of Jacksonville, has been transferred to the U. S. Veterans' Hospital, Fort MacKenzie, Sheridan, Wyo., where he will be clinical director.——Dr. Henry A. Merkel, Wilmington, has been appointed physician to the Soldiers' Widows' Home, to succeed Dr. Charles J. Carlin.

Society News.—Dr. Roden Robinson Duff, Chicago, addressed the Adams County Medical Society, Quincy, November 9, on "The Management of Common Fractures."——Dr. Harold M. Camp, secretary, Illinois State Medical Society, addressed the Chamber of Commerce of Cambridge, November 16, on "Medical Service in Illinois."

Chicago

Chemistry Luncheon.—At a luncheon, December 5, at the University of Chicago, given by President Max Mason, Dr. William H. Mayo, Rochester, Minn., gave an address on "Chemistry in Medicine"; Arthur D. Little, D.Chem., Cambridge, formerly president of the American Chemical Society, on "Chemistry in Industry," and Julius Stieglitz, Ph.D., head of the department of chemistry, University of Chicago, on "Chemistry in the University." Following luncheon, the guests were taken through Kent Chemical Laboratory, where each man engaged in research demonstrated his particular problem.

Dr. Hedblom Appointed Professor of Surgery at Illinois.—The board of regents of the University of Wisconsin announced, December 2, the resignation of Dr. Carl Hedblom, who has been professor of surgery in that institution since June 26, 1924. Dr. Hedblom has been appointed professor of surgery at the University of Illinois College of Medicine, Chicago, and will take up his duties, February 1, 1926. Dr. Hedblom is a graduate of Colorado College (B.A.), Harvard University (M.D.), and the University of Minnesota (Ph.D.); he was an intern in the Massachusetts General Hospital, Boston; professor of surgery in the Harvard Medical Schools of China from 1913 to 1916; appointed head of the section on general thoracic surgery at the Mayo Foundation in 1919 and was assistant professor of surgery in the University of Minnesota.

Health Pageant.—Sponsored by the Seventh District Illinois Federation of Women's Clubs and under the auspices of the Northwest Branch of the Chicago Medical Society and the Northwest Branch of the Chicago Dental Society, an All-Community Health Pageant was held, December 3-5, at the Logan Square Masonic Temple. Among the features of the pageant were free medical and dental examinations for children and adults, and a prize was given for the healthiest man and woman past 70 who lived on the northwest side. Among the speakers were Dr. Thomas Parran, Jr., U. S. Public Health Service, whose subject was "Cooperation"; Dr. Abraham Myerson, professor of neurology and neuropathology, Tufts College Medical School, Boston; Charles N. Johnson, D.D.S., formerly president of the American Dental Association; Dr. Claude C. Pierce, U. S. Public Health Service; Dr. Borden S. Veeder, St. Louis, and Dr. Morris Fishbein. The physicians and dentists were guests of the business men of the Northwest side at a dinner, Friday evening.

INDIANA

Joint Meeting with Dentists.—Dr. Joseph C. Bloodgood, Johns Hopkins University Medical School, Baltimore, was guest of honor at a joint meeting of the First District Dental Society and the Vanderburgh County Medical Society, Evansville, December 4, on which occasion he gave an address on "Prevention of Cancer of the Mouth"; among others Dr. Bernard D. Ravdin spoke on "Stomatologic Problems Causing Eye, Ear, Nose and Throat Complications" and William G. Downs, Jr., D.D.S., on "Stomatology, the Common Ground in Medicine and Dentistry"; it was decided to call a meeting of dentists and physicians in this locality for the purpose of forming a stomatologic association, which, it is said, would be the first in the Middle West.

IOWA

Society News.—Dr. Daniel G. Lass, Ocheyedan, has been elected president of the Northwest Iowa Medical Association, and Dr. Walter R. Brock, Sheldon, vice president.

Personal.—Dr. Jeannette Jongewaard has been appointed medical adviser at Iowa State College, succeeding Dr. Mary J. Sheldon, resigned.——Dr. Jesse L. McElroy, formerly of St. Mark's Hospital, New York, arrived in Iowa City, November 12, to take up the duties of superintendent of the University of Iowa General Hospital, succeeding Dr. Bert W. Caldwell, resigned.——Dr. Lee E. Shafer, Davenport, has been elected president of the Scott County Medical Society.

KENTUCKY

New Health Officer for Louisville.—The board of public safety, November 28, approved the appointment of Dr. Clarence H. Harris as city health officer of Louisville, to succeed Dr. Evan Ellis Owen, whose resignation was accepted as of December 1. Dr. Harris is a past president and treasurer of the Jefferson County Medical Society, and former county health officer.

Personal.—Dr. Oliver P. Henry tendered his resignation as county health officer of Mount Sterling, October 30.——Dr. Felix G. Fowler was appointed physician for the negro schools by the board of public safety at Louisville, November 10, to succeed Dr. Percy R. Peters.——Dr. Robert D. Higgins, Ashland, has been reelected director of the Boyd County Board of Health for a period of four years.

LOUISIANA

Personal.—Dr. E. Denegre Martin, New Orleans, was elected president of the Southern States Association of Railway Surgeons at the meeting of the Southern Medical Association in Dallas, Texas, November 9-12.——Mr. John M. Pugh took up his new duties as director of the dairy division of the Louisiana State Board of Health, December 1.——Dr. Lucy S. Hill, Washington, D. C., recently joined the staff of the bureau of child hygiene, infancy and maternity division of the state board of health.

New Building for Charity Hospital.—A cordial invitation was extended to the public to visit the new $335,000 building of the Charity Hospital, New Orleans, November 30, previous to its being placed in service the following day. The building faces on Tulane Avenue, and has a capacity of 120 beds, which will be for white female medical patients. An appeal to the public for funds for this building made in March, 1923, resulted in contributions of more than $289,000 to which interest and other small sums were added, making about $310,000. The deficit will be reduced by the payment of a pledge from Jefferson parish for $10,000; Tangipahoa parish also pledged by a former police jury, $15,000, according to the *Times-Picayune*. The hospital now has a total of 1,250 beds.

THE SLIP FOR SUBSCRIPTION AND FELLOWSHIP DUES IS IN THIS ISSUE.

MICHIGAN

Personal.—At the recent convention in Lansing of public health officers, Dr. Charles A. Neafie, Pontiac, was elected president of the Michigan Public Health Association; Dr. William J. V. Deacon of the Michigan State Department of Health, secretary-treasurer, and among others, Dr. John Sundwall, Ann Arbor, professor of hygiene and public health, University of Michigan Medical School, was elected a director.

MINNESOTA

Society News.—Dr. Naboth O. Pearce addressed the Hennepin County Medical Society, November 25, on "Dietary Considerations in the Care of Diabetic Children," and Dr. Jennings C. Litzenberg, on "Some Newer Phases of Sterility."——Dr. Angus W. Morrison addressed the Hennepin County Medical Society, December 2, on "Mental Hygiene and the Physician," and Dr. Richard R. Cranmer on "Differential Diagnosis in Acute Abdominal Disease."——At the regular meeting of the Minneapolis Academy of Medicine at the Town and Country Club, Minneapolis, December 9, Dr. Winford P. Larson gave an address on "The Value of Surface Tension Depressants in Detoxifying Bacterial Toxins for Immunization," and Dr. George E. Fahr on "The Fatigue Factor in Cardiac Failure."

MISSOURI

The Adcox Confession (Continued).—When the United States entered the World War, the demand for fraudulent diplomas doubled. Dr. Robert Adcox says in the St. Louis *Star*. The chiropractors, osteopaths, mechanotherapy fakers, and electrotherapy and hydrotherapy quacks, "who had been clinging to the coat tails of medicine," wanted commissions in the army medical corps. He says that low-grade colleges graduated ignoramuses in droves and that students in first-class institutions deserted their classes to go to "mill schools" to graduate or to purchase diplomas outright. Adcox says that hundreds of quacks and charlatans wore uniforms, that some young chap who felt called to serve his country rung his door bell every few minutes, and that he did his "bit" by assisting the government to obtain "the needed doctors." Now at 63, "in these days of life's autumn," Adcox says he is awakened by a cry which others cannot hear but which he knows is that of victims who died in training camps—victims of charlatans. The demand for diplomas continued after the armistice, it is said, so it was necessary to open new agencies and branch offices of the "National Medical Diploma Mill." Owen T. Owen was active in Chicago; Frank J. Kenney in Washington and Baltimore; Ralph A. Voigt, who now had his M.D. and was out of the army, in Kansas City, and others were "on the ground" in Boston, New York, Philadelphia, Los Angeles, New Orleans, Houston, Dallas, Minneapolis, Detroit, San Francisco, Memphis and a score of other cities. Barred from association with respectable members of the profession, the charlatans felt the urge to join something that would offer at least a cloak of respectability, so "medical societies" multiplied like rabbits. Thus there were created hybrid societies which for a fee issued certificates of membership. "The Incorporated Society of Science, Letters and Arts of London, Limited," and the "Italian Physico-Chemical Academy" continued to sell "their stuff" long after being exposed, the former conferring an "F.S.S.C. Lond.," which any quack could purchase for $5 by writing to London. These letters stand for fellow of the Incorporated Society of Science, Letters and Arts of London, and mean nothing. The "Academie Physico-Chemique Italienne" was operated by two nonscientific men, who mailed hundreds of letters from Palermo to American physicians, informing them that they had been nominated as honorary members of the academie by the council and had had conferred a medal and diploma. Imagine, Adcox says, how the quacks went after these medals. But they were caught by a joker in the constitution and had to pay a fee for their honors. The general public and even the public health authorities have no idea, he says, of the extent of operations of these mills. With some state boards willing to accept almost any credentials, the problem confronting Adcox was how to obtain licenses for persons too ignorant to pass an examination. Having been offered $1,000 for a license to practice in a Southern state, Adcox decided to enter this field.

NEW YORK

Hospital News.—The Troy Hospital, Troy, celebrated its diamond jubilee, November 18, at Music Hall, with appropriate ceremonies, and among the speakers were Dr. Joseph Collins, New York, and the Hon. Alfred J. Talley of the Court of General Sessions, New York. Dr. Melville D. Dickinson, chief of the medical staff of the hospital, presented Mayor Clinton, who presided at the ceremonies.

Safety Congress.—The Ninth Annual Industrial Safety Congress and Exhibit was held in Syracuse, November 30-December 3, under the auspices of the State Department of Labor and with the cooperation of the Medical Society of the State of New York and the New York State Society of Industrial Hygiene. There were discussions, the reading of papers and a safety exhibit. Industrial accidents in New York last year numbered more than 374,000.

New York City

Physicians' Buildings.—A twenty-two-story office building for the use of physicians is to be erected on Fifty-Ninth Street between Sixth and Seventh avenues, facing Central Park.——A new office building for Brooklyn physicians is to be erected at 128-130 Livingston Street by a firm of New York builders.

Personal.—Dr. Samuel Weiss has been appointed adjunct professor of gastro-enterology at the New York Polyclinic Medical School and Hospital.——Dr. Adolph Jacoby has been promoted to assistant professor of gynecology on the staff of Dr. Walter T. Dannreuther at the New York Post-Graduate Medical School and Hospital.——Friends of Dr. Charles Norris, the city's chief medical examiner, gave a dinner in his honor, November 28, at the Hotel McAlpin. Dr. Norris recently returned from abroad, according to the New York *Medical Week*, fully restored in health.——Dr. William Seaman Bainbridge gave a dinner in honor of Sir William Arbuthnot Lane, London, at the Union League Club, November 25, which was attended by sixty-five physicians.

Society News.—Dr. A. M. Pennell, Bannu, Hindustan, addressed the Women's Medical Association at the New York Academy of Medicine, November 18, on "Medical Work Among the Women of India."——Dr. Binford Throne has been elected president of the Brooklyn Dermatological Society; Dr. John C. Graham, vice president, and Dr. Ernest Almore Gauvain, secretary-treasurer.——At the annual meeting of the New York County Medical Society, November 23, Dr. William P. Healy was elected president; Drs. Henry S. Patterson and John Douglas, vice presidents; Dr. Daniel S. Dougherty, secretary, and Dr. James Pederson, treasurer.——Dr. O. Paul Humpstone has been elected president of the Kings County Medical Society to succeed Dr. John E. Jennings; Dr. Thurston S. Welton, vice president, and Dr. Thomas M. Brennan, secretary, reelected.——Dr. Martin L. Janes addressed the Ward's Island Psychiatric Society, November 25, on "The Therapeutic Value of Blood Transfusion in Certain Psychoses."——At the annual election of the New York Academy of Medicine, December 3, Dr. Charles A. Elsberg was chosen vice president for three years, and Drs. Nathan E. Brill and Eugene H. Pool trustees for five years.

OHIO

Medical Mayors.—At the elections in Ohio last month, Dr. Samuel M. Mehaffey was elected mayor of Dennison; Dr. Claud C. Craig, mayor of Urbana, and Dr. Charles T. Gallagher, mayor of Mount Sterling.

Joint Study of Expert Testimony.—The Cleveland Bar Association and the Academy of Medicine of Cleveland are conducting a study of problems involved in medical expert testimony. The committee will study these questions: (1) What has been done in other states in the past? (2) If an impartial group of medical expert witnesses could be used, should this group be established by the court or by the medical profession through its organizations? (3) What would be the effect of such a group on procedure in trial cases? (4) How should such a group be compensated for their services? and (5) What questions of constitutionality would be involved in any proposed change? The members of the committee are Drs. George E. Follansbee, Vernon C. Rowland, Charles W. Stone and Jacob E. Tuckerman, and Paul Holland, John A. Cline, C. A. Niman and Herman J. Nord of the bar association.

Society News.—Dr. Carroll W. De Courcy, Cincinnati, addressed the Wood County Medical Society, Bowling Green, November 19, on "Arthritis." Dr. Frank V. Boyle was elected president of the society, Dr. Edward H. Mercer, vice president, and Dr. Orval I. Nesbit, secretary-treasurer.——Dr. David H. Morgan will address the Medical Section of the Summit County Medical Society, Akron, December 22, on "Encephalitis Lethargica and Its Sequelae"; Dr. James G. Blower will address the Surgical Section, December 8, at the People's Hospital on "Cancer of the Breast."——Members of the Jefferson County Medical Society gave a testimonial dinner in Steubenville, recently, to honor Dr. James C. M. Floyd, who has completed fifty years in the practice of medicine, forty-three of which have been spent in the city of Steubenville; flowers and a silver loving cup were presented to Dr. Floyd, and among those who spoke were Dr. Benjamin A. McClelland, Xenia; Dr. Benjamin F. Harden, Wellsburg.

OKLAHOMA

New Full-Time Health Officers.—The three new full-time county health units to be established soon in McCurtain, Bryan and Kay counties will be in charge of Dr. Robert D. Williams, Dr. Grady F. Mathews, and Dr. David M. Cowgill, respectively.

Medical School Building Opened.—The new $100,000 medical building of the University of Oklahoma at Norman, which was completed last February, was formally opened to the public, November 23, when more than 4,000 persons saw the various departments in operation. It is a reenforced concrete structure with brick veneer tile roof, three floors and a basement, and is one of three units of a proposed building which will be completed when funds are available.

Birth Registration.—Six representatives of the state department of public health are now engaged in making a state-wide survey to determine the completeness of registration of births. They are visiting every school in the state to interest parents in birth registration. The cooperation also of every county superintendent of health and the clergy have been obtained; 500 local registrars will assist in obtaining the support of women's clubs; every organized community center will be urged to see that the exact date and place of birth of every child under 1 year of age is forwarded to the state department, and an addressed postcard will be placed in every home in the state where a birth has occurred in the last year.

Philadelphia

Dr. Lloyd Honored.—Members of the Blockley Ex-Resident Association, at their thirty-ninth annual banquet, December 1, honored Dr. James H. Lloyd on the occasion of his birthday; Dr. Lloyd has served for many years as chief of the neurologic service; among the speakers were Dr. Daniel J. McCarthy, president and toastmaster; Dr. Charles W. Burr, chief of the neurologic service in 1896; Dr. Joseph C. Doane, superintendent, Philadelphia General Hospital; Dr. George H. Fox, New York, a resident in 1869, and Dr. Isaac H. Moore, Seattle, '78. Dr. David Riesman was elected president for the coming year.

Medical Lectures. — Dr. Simon Flexner, director of the Rockefeller Institute, delivered the third Weir Mitchell Oration, December 9, at the College of Physicians, on "The Advancement of Epidemiology Through Experiment."——Dr. Edward W. Archibald, professor and director of the department of surgery, McGill University Faculty of Medicine, Montreal, delivered the Mutter Lecture of the College of Physicians, December 11, on "The Pathology of the Compressed Lung; Lipoidal Injections of the Tuberculous Lung; Results of Surgical Treatment in Unilateral Pulmonary Tuberculosis."——Dr. William F. Rienhoff, Jr., department of surgery, Johns Hopkins University Medical School, Baltimore, addressed the Pathological Society, December 10, on "The Histologic Changes in Exophthalmic Goiter Following the Administration of Iodin."

THE SLIP FOR SUBSCRIPTION AND FELLOWSHIP DUES IS IN THIS ISSUE.

WASHINGTON

Personal.—Dr. Percy P. Cooley, Monroe, who was recently appointed as health officer of Snohomish County and physician at the Aldercrest Sanatorium, to take effect, Jan. 1, 1926, has resigned.

Society News.—Dr. C. C. Tiffin, Seattle, who has been studying cretinism and goiter in Switzerland, addressed the Jackson County Medical Society, Medford, Ore., November 18, and the Thurston County Medical Society, Olympia, November 20, on "Cretinism and Its Relation to Goiter."

Attempt to Restore Sanipractors' Licenses.—A bill introduced in the legislature now in session, if passed, will restore about ninety licenses of sanipractors, which were recently revoked for having been obtained from a "diploma mill" in Seattle. The bill would create also a separate board of examiners for sanipractors, which would offer examinations in anatomy, physiology, hygiene, pathology, kinesiology, herbology, obstetrics, toxicology and other subjects. Sanipractic is defined as "the science and art of applied prophylactic and therapeutic sanitation, which enable the physician to direct, advise, prescribe or apply food, water, roots, herbs, light, heat, exercise, active and passive, manipulation, adjusting tissue, vital organs and anatomical structure by manual, electrical instruments or appliances, or other natural agency, to assist nature restore a psychological and physiological interfunction." The house committee has reported the bill unfavorably.

WYOMING

Outbreak of Botulism.—The four children of Mr. and Mrs. A. H. Collins, Rawlins, are reported to have died suddenly of botulism following the eating of sandwiches made from canned meat, November 21. The father, who was also very ill, recovered. State and local health officials are investigating the entire stock of canned meat in the city.

GENERAL

New Editor Appointed.—The board of trustees of the American Dental Association at the recent annual meeting, Louisville, Ky., elected Charles N. Johnson, D.D.S., Chicago, editor of the *Journal of the American Dental Association*, to succeed Dr. Otto U. King, who becomes business manager of the Association and retains the office of general secretary. Dr. Johnson was formerly president of the American Dental Association and for many years editor of *Dental Review*.

Regional Institute for Tuberculosis Workers.—Under the auspices of the National Tuberculosis Association and the tuberculosis associations of the New England States, New York, New Jersey, New York City and Brooklyn, there will be an institute for tuberculosis workers held in New York, Jan. 4-20, 1926, which will be conducted by round table conferences. The courses include three divisions: (1) "Methods of Antituberculosis Work"; (2) "Programs of Antituberculosis Work"; (3) "Relation of the Tuberculosis Campaign to Other Social and Public Health Movements." Membership in the institute will be by invitation following personal application, which should be sent to Philip P. Jacobs, 370 Seventh Avenue, New York.

News of Epidemics.—An outbreak of eight cases of smallpox in the village of Sawyerville, Ala., was reported, November 19, and more than 200 cases of smallpox in Pottawattamie County, Iowa, November 29, the latter of a mild type. ——The city and county health officers of Evansville, Ind., took steps Thanksgiving Day to check an epidemic of more than forty cases of scarlet fever in the city and about twenty cases in rural communities. There were seven new cases of scarlet fever reported in the thirty-six hours, ending November 28, in Evansville, bringing the number of cases in the city to ninety.——An epidemic of fourteen cases of scarlet fever was reported in the village of Morgan, N. J., November 25, and another in the Wilson School, Camden, N. J., on the same date.——There were fourteen cases of scarlet fever in quarantine in Muscatine, Iowa, November 28.——The city schools of Carlisle, Ky., were ordered closed by the county health officer for a few days, November 25, to permit fumigation of the buildings to prevent the spread of diphtheria; at that time there were three cases in that city.——The public schools of McGuffey, Ohio, were closed, November 20, it is reported, on account of an epidemic of scarlet fever.

"Tranquillity."—It has been proposed that the national home for aged and incapacited physicians shall be "home" in the fullest sense of the word and that it shall be called "Tranquillity." The first unit, founded four years ago in Caneada, N. Y., has been successful. There have been hundreds of cases that could not be accommodated. It has been necessary to appeal to the public to secure funds to build a home of national size with smaller units throughout the country to meet sectional needs. The project was laid before some of the ablest physicians and before a number of prominent persons outside the medical profession, and their unanimous belief was that the public would support a campaign to raise funds. The campaign was recently opened with headquarters in the Times Building, Forty-Second Street and Broadway, New York City, to which office subscriptions should be sent. Several million dollars will be required. The home is not to be in any sense luxurious. It will be a plain, substantial institution, well furnished, to meet the average wants of the average man. The inmates will be encouraged to employ their time; a well appointed laboratory is contemplated wherein those whose faculties permit may still pursue their studies with the hope that medicine may benefit by their investigations; it is also contemplated that arrangements shall be made for physicians who, falling ill, may need a haven in which to win back their health. Those who subscribe $5,000 will be designated as Benefactors; those who subscribe $2,500 will be designated as Donors; $1,000, Patrons; $500, Life Members, and $100, Sustaining Members. None of the officers or directors of the home are paid as such nor will they participate in the funds subscribed.

Society News.—At the annual meeting of the Central States Pediatric Society, Chicago, November 6-7, Dr. George M. Tuttle, St. Louis, was elected president; Dr. Frederick C. Rodda, Minneapolis, vice president, and Dr. Henry T. Price, Pittsburgh, secretary-treasurer, reelected.——Dr. James Y. Welborn, Evansville, Ind., was elected president of the Ohio Valley Medical Association at the twenty-sixth annual meeting in Indianapolis, November 11; Drs. Daniel N. Eisendrath, Chicago, Emmet F. Horine, Louisville, Ky., and Dr. Joseph E. Pirrung, Cincinnati, vice presidents, and Dr. Benjamin L. W. Floyd, Evansville, Ind., secretary-treasurer, reelected. Among the speakers were Dr. Joseph Miller, Chicago; Dr. Bethuel B. Vincent Lyon, Philadelphia; Dr. William H. Foreman, Indianapolis, and Dr. Martin H. Fischer, Cincinnati. The next annual meeting will be in Louisville.——The Midwinter Session of the American Electrotherapeutic Association and affiliated Eastern societies will be in the New York Academy of Medicine, Jan. 6-7, 1926; there will be clinical demonstrations at the Reconstruction and the Beekman Street hospitals; among others, Dr. William

B. Snow, New York, will discuss "Treatment of Local Septic Infection"; Dr. Sinclair Tousey, New York, "Dangers of Roentgen Rays"; Dr. William T. Johnson, Philadelphia, "The Value of Static Currents in Preventing Baldness"; Dr. William D. McFee, Haverhill, Mass., "Physiotherapy in the Treatment of Arthritis"; Dr. Morris Fishbein, editor of THE JOURNAL, "The Council on Physical Therapy"; Dr. Wendell C. Phillips, New York, President-Elect of the American Medical Association, and Dr. Horatio B. Williams, Dalton, professor of physiology, Columbia University College of Physicians and Surgeons, "The Council on Physical Therapy." ——The American Psychological Association will hold its annual meeting, December 28-30, at Cornell University, Ithaca, N. Y. The annual dinner and the presidential smoker will be Tuesday evening.

Bequests and Donations.—The following bequests and donations have been announced recently:

The Huggins Hospital, Wolfeboro, N. H., $2,000, by the will of the late Lyford A. Merrow for the benefit of patients from Ossipee, and $5,000 to the Boston University, and $10,000 for a fund, the interest on which is to assist young persons from Ossipee to obtain an education.

The New England Deaconess Hospital, Boston, the residuary estate after certain bequests to relatives and certain churches, of Elzora A. Purington, Portland, Me.

The Springfield Hospital, Springfield, Vt., the First Methodist Church of Springfield and the town of Springfield, a total of $24,000, by the will of the late C. F. Wilson, New York.

The Virginia Baptist Hospital, Lynchburg, Va., a gift of $75,000 from Mrs. Annie C. Mundy, Natural Bridge, Va., for the construction of a second unit as a memorial to her husband, her daughter and self.

Jefferson Hospital, $5,000, to establish a bed in his mother's memory, by the will of the late Dr. Duncan L. Despard, Philadelphia.

The Home for Incurables, Chestnut Hill, Pa., $5,000; the Pennsylvania Institution for Instruction of the Blind, $2,000, and the Chapin Home for the Aged Blind and the West Philadelphia Homeopathic Hospital, each $1,000, by the will of Miss Louisa T. Pfaff, Philadelphia.

The Pennsylvania Hospital, $50,000, and the Children's Hospital, Philadelphia, $250,000, by the will of the late Wilson Catherwood.

The Hospital for Ruptured and Crippled Children, New York, $20,000, and the New York Association for the Blind, $25,000, by the will of the late William Carr.

Lenox Hill Hospital, New York, $50,000, by the will of the late Rudolph J. Schaefer.

The Amsterdam City Hospital and the Loomis Sanatorium, $5,000 each, by the will of the late Nelson S. Clark.

The Home for the Aged of the Little Sisters of the Poor, New York, $5,000; All Souls Hospital, Morristown, N. J., and St. Mary's Catholic Orphan Asylum, Newark, N. J., each $3,000, by the will of the late Bernard J. Coleman.

The Jewish Hospital, Philadelphia, $100,000, for the erection of a wing for the aged and infirm, and the Jewish Foster Home and Orphan's Asylum, Philadelphia, $60,000, by the will of Miss Julia Mayer.

The Children's Home, New York, $2,000, by the will of the late Christian Kress.

St. Luke's Hospital, Bellingham, Wash., $10,000, by the will of the late John Williams, Deming, N. M.

Mr. Benjamin N. Duke, Durham and New York, has recently contributed $5,000 to cancel debts of the new Lincoln Hosital at Durham for colored people. In fireproof structure and character of building and equipment this new hospital ranks with the best in the state. Mr. Duke had previously contributed $25,000 in its construction.

The Salem Hospital, Salem, Mass., $150,000, the Society for the Relief of Aged and Destitute Women, Salem, $10,000, and the Bertram Home for Aged Men, $5,000, by the will of the late Robert Osgood of Salem.

The Elliott Hospital, Manchester, N. H., $10,000, of which a sufficient sum shall be set aside for a free bed for inhabitants from Candia, by the will of the late Henry W. Moore of Candia.

St. Barnabas Hospital, Newark, N. J., $15,000, by the will of the late Charles H. Hampton of East Orange.

Seton Hospital, and Sisters of the Poor of St. Francis and Home for the Aged of the Little Sisters of the Poor, New York, with others, share in the residuary estate, amounting to about $8,000, of the late Mary Jackson.

Lake County Memorial Hospital, Painesville, Ohio, $10,000, by the will of the late Stella L. Cummings, to endow a charity ward.

The will of the late Marion E. Griffin, Spencer, Iowa, provides for a bequest of $50,000 to equip a county hospital, to be erected if authorized by a vote of the people of Clay County within five years; $5,000 to the Orphans' Home of Council Bluffs, Iowa; $5,000 to the American Home Finding Society, Ottumwa, Iowa; $10,000 to the Salvation Army of Iowa, and $10,000 to the American Red Cross of Iowa.

Mount Sinai Hospital, New York, $1,000, by the will of the late Mrs. Clara A. Fenchtwanger.

St. Catherine's Hospital, Brooklyn, $800, by the will of the late Helena Pappon, Jamaica, L. I.

Mount Sinai Hospital, New York, $5,000; Presbyterian Hospital and St. Luke's Hospital, New York, and the New York Association for the Blind, each $500; the United Hebrew Charities, New York, $2,000, by the will of the late Morris J. Hirsh.

The Associated Hospitals of New York, $169,827, and the Servants of Relief for Incurable Cancer, New York, $339,654, by the will of the late Henry Evans.

The Fifth Avenue Hospital, New York, $200, by the will of the late Marguerite A. Goeks.

The Greenwich Hospital, Connecticut, and the Roosevelt Hospital of New York, each $5,000, by the will of the late Elijah W. Sells.

The Skin and Cancer Hospital, New York, and the Old Ladies' Home, Hackensack, N. J., each $1,500, by the will of the late John Flood.

The Skin and Cancer Hospital, New York, and the Old Ladies' Home, Hackensack, N. J., each $1,500, by the will of the late Edward F. Gordon.

The Harvard University Medical School, Boston, $5,000, by the will of the late Dr. John W. Elliott.

Mount Sinai Hospital, New York, $3,000; the Montefiore Home for Chronic Invalids and the Home for Aged Infirm Hebrews, $2,000 each; the Lebanon Hospital Association and Beth Israel Hospital, $1,000 each; the Hebrew Orphan Asylum, $5,000; the Henry Street Settlement, the Association for the Blind, the Tuskegee Institute and the Jewish Consumptive Relief Society of Denver, each $500, by the will of the late Moses Ottinger, New York.

FOREIGN

Gift for Medical Building.—Mr. M. Tatsuke has donated 500,000 yen for the erection of a hospital and medical institute building in Osaka at the Kyoto Imperial University, and the gift has been accepted. The medical institute probably will be named the Tatsuki Institute.

Record Low Birth Rate in England.—The registrar general of England issued statistics, December 2, it is reported, which showed that fewer children were born in England last year than in any previous year on record except during the World War. The birth rate was said to be 18.8 per thousand, which is slightly below that of France (18.9).

Dr. Farkas Receives Orthopedic Prize.—The five-year prize known as "The Humbert I Prize" has been awarded to Dr. Aladar Farkas, Budapest, for his work on "Causes and Pathogenesis of Scoliosis" by a committee made up of Profs. Vittorio Putti, Riccardo D. Vedova and Francesco Delitala. The previous recipients of this prize have been Drs. Vulpius, Schulthess, Vangetti and Murk Jansen (Germany, Switzerland, Italy and Netherlands).

Acid Rain.—During the last year, according to the *Lancet*, 615 tons of organic matter—nitrates, bitumen, calcium salts, sulphates and chlorids—came down with the rain on each square mile of Liverpool's most densely populated districts. The bronze of the Queen Victoria monument was so acted on by the sulphuric acid in the rain water that the copper sulphate formed sunk to a distance of 4 inches in the Portland stone on which the monument stands.

THE SLIP FOR SUBSCRIPTION AND FELLOWSHIP DUES IS IN THIS ISSUE.

Taxes Peril the Nobel Prizes.—For the first time since the Nobel prizes were given twenty-four years ago, the directors have decided this year to withhold all five of the prizes. *Science* notes that the reason for this decision is said to be a lack of qualified candidates and a need for funds for the Nobel Library and the Physical and Chemical Institute, both of which were founded in Stockholm as a part of the Nobel memorial. High taxes seem to be imperiling the Nobel prizes, it is said. The taxes on the prizes in 1901 were 83,042 crowns and in 1923 were 578,006 crowns, whereas in this period the prizes decreased from 709,234 to 574,676 crowns. The Nobel family has petitioned the Stockholm government to exempt the foundation from taxes. There are Nobel prizes in physics and chemistry, awarded by the Swedish Academy of Science; in medicine or physiology, awarded by the Stockholm Faculty of Medicine; in literature, awarded by the Swedish Academy of Literature, and the Nobel peace prize, awarded by a committee of five elected by the Norwegian Storthing.

Deaths in Other Countries

Dr. **H. Fehling**, Baden, for many years professor of gynecology at Strasbourg, aged 78.——Dr. **L. W. Weber**, director of the municipal hospital for nervous affections, Chemnitz. ——Dr. **H. Kuhnt**, emeritus professor of ophthalmology, Bonn, one of the two founders of the *Zeitschrift für Augenheilkunde* in 1899.——Dr. **P. J. Schultz**, chief of the orthopedic department of the Münster surgical clinic and author of works on deformities and bone lesions. His skull was fractured in a fall during a boxing bout.——Dr. **Paul Heger**, emeritus professor of physiology, Brussels, aged 80.——Dr. **Lambinet**, Liége, chief of the bacteriologic service at the university and a pioneer in study of hookworm.——Dr. **Boppe**, Nancy, army *médecin inspecteur*, killed in an automobile accident.——Dr. **F. St. George Mivart**, London, formerly medical officer of the Ministry of Health, November 5, aged 70.——Dr. **John Newport Langley**, professor of physiology, University of Cambridge for the last twenty-two years, for more than thirty years editor of the *Journal of Physiology*, formerly president of the new Neurological Society of Great Britain, and Baly Medalist of the Royal College of Physicians of London in 1903, November 5, aged 73.——Dr. **Edward J. Donville**, consulting surgeon to the Royal Devon and Exeter Hospital, recently, aged 76.

CORRECTION

Chief Surgeon at Union Hospital.—THE JOURNAL noted, September 26, that Dr. Duke R. Gaskins, Harrisburg, Ill., had been appointed chief surgeon and manager of the Union Hospital, West Frankfort. Dr. J. E. Williams is chief surgeon at this hospital, and Dr. Gaskins' appointment was as assistant surgeon and manager.

Government Services

Annual Report of Surgeon General

The mortality and the venereal disease rates in the army are the lowest in history, according to the annual report of Surg.-Gen. Merritte W. Ireland. The general death rate for 1924 was 3.82 per thousand, as compared with 3.91 the preceding year, when the rate for the first time in army history fell below 4 per thousand. The death rate for disease in 1924 was 1.94 per thousand, which is the first time it has been below 2 per thousand. In the last twenty-five years the incidence of venereal diseases has declined 69 per cent. and that of malaria 98.7 per cent. During the year, the medical department of the army demonstrated the method of transmission of dengue by mosquitos, and the research on this problem was as complete, according to medical officers, as that conducted on yellow fever by Walter Reed and his associates in Cuba following the Spanish-American War. Relatively greater progress has been made in the army in the prevention of deaths from disease than from external causes. Suicide held its place as the chief cause of death, with tuberculosis second, automobile accidents third, and airplane and balloon accidents fourth.

The report showed that in the eight years, 1917 to 1924, there were 874 deaths resulting from airplane accidents, not including World War battle casualties; of that number, 520 were officers. For the last five years the air accident death rate for officers was 26.95 per thousand, while in 1924 the rate was 21.04. "The ratio of crashes for the heavier-than-air machines," General Ireland said, "has decreased from one crash to 200 flying hours in 1921, to 1 crash to 500 flying hours in 1924, and the fatalities from one to 955 flying hours in 1921 to one to 3,365 flying hours in 1924." A tabular presentation of the 256 crashes in 1924 showed that 138 occurred in landing, that "poor piloting and inexperience" was held responsible for 84, and engine trouble for 58. While 40 were killed or died as a result of injuries, 35 were seriously injured and 55 were slightly injured; 284 persons in planes, which crashed, escaped injury entirely. Establishment of airplane ambulances at each air service station is recommended, together with the creation of an airplane ambulance squadron of twenty-five planes for each field army organization. The planes would have a capacity for six litters or eight sitting patients. A squadron of this type, the report states, "can transport as many patients 100 miles in one hour as a railway hospital train in four or more hours," and can receive patients much nearer the fighting area.

Veteran's Bureau Resignations

The following medical officers of the U. S. Medical Bureau resigned on the dates indicated: Dr. James S. Burger, hospital No. 65, St. Paul, Minn., October 31; Dr. Howard T. Child, hospital No. 95, Northampton, Mass., August 8; Dr. Lyle G. Ellis, hospital No. 97, Chillicothe, Ohio, September 28; Dr. John H. Graff, September 19; Dr. Antonio Mayoral, hospital No. 80, Fort Lyon, Colo., September 15; Dr. Walter D. Martin, Central office, Washington, D. C., July 31; Dr. Oliver J. Miller, hospital No. 27, Alexandria, La., August 30; Dr. Elmer L. Smythe, hospital No. 59, Tacoma, Wash., October 15, and Dr. William M. Stinson, hospital No. 72, Harrison, Mont., August 15.

Army Personal

Major Charles E. MacDonald, M. C., has been recommended to the adjutant general by Mr. George Curry of the International Boundary Committee for the Distinguished Service Cross for service with him in Samar, P. I., from 1905 to 1907.

Noncommissioned Officers of Medical Department

A course of instruction for noncommissioned officers of the army medical department has been started at Carlisle Barracks, Pa., to assist in raising the standard of noncommissioned officers. This year's class has fifty-two members —twenty-six from the regular army, twenty-two from the National Guard, and four from the U. S. Navy. At the opening exercises of the school, addresses were given by Lieut.-Col. Charles R. Reynolds, Commandant, and Major Garfield L. McKinney, director of the school. The total number of demerits any member of the class can get and still be eligible for graduation from the course is twenty-five.

Lay Radiographers and Medical Reports

The Society of Radiographers has passed a rule preventing lay members from making any report or diagnosis on any roentgenogram or screen examination, but it was agreed that this rule should be interpreted to allow a lay radiographer (in the absence of a medical radiologist) to describe to a physician the appearances seen in a roentgen-ray examination, so as to assist him in making a diagnosis. The Institution of Electrical Engineers, which took part in the foundation of the Society of Radiographers and nominated six out of the eighteen members of its council, has withdrawn its nominees and terminated the institution's connection with the society, because it considered that the new rule would materially lower the professional status of nonmedical radiographers. An attempt had been made previously by a representative of the institution to modify the proposed rule by moving that it be amended so as not to be applicable to members of the society who had been engaged in roentgen-ray work for not less than fifteen years. Such members would thus be allowed to interpret roentgenograms, make screen examinations and diagnoses, and treat patients. Objection was taken to this by the General Medical Council, which pointed out that if such a clause was inserted in the rule the medical members of the society would find themselves in the untenable position of associating with unqualified persons who were performing medical functions without medical training or without immediate personal medical supervision. This decision the medical members of the Society of Radiographers could not, of course, dispute. Nevertheless the Institution of Electrical Engineers maintained its position. A large proportion of the radiographers, however, have expressed agreement with the new rule.

The Demand of Osteopaths for Registration

As stated in previous letters, there are now a large number of osteopaths in this country, and a few physicians have joined their ranks. Osteopathy is evidently, for the time at any rate, a paying proposition, and the agitation for the legal status that would be conferred by state registration continues. In a letter to the *Times* advocating registration, the vice president of the British Osteopathic Association has the audacity to describe osteopathy as "a system which has scientifically classified the entire field of mechanicotherapeutics" and refers to the manifesto of his association in which osteopathy is defined "as that system of the art of healing which regards the structural integrity of the body as the most important single factor in the maintenance of health." He asserts that osteopaths have to undergo a training as rigorous as that required in any other branch of the medical profession. He complains that there are three times as many unqualified "pretenders" as there are "qualified osteopaths." He goes on to talk of "the attacks of the general medical council on the fully qualified osteopaths." This is absurd, for the general council does not concern itself with irregular practitioners at all and, indeed, has no power over them, its jurisdiction being confined to qualified physicians. In a letter to the *Times,* written with all his characteristic cleverness, Bernard Shaw, who is always a destructive critic and an advocate of the revolutionary and the paradoxical, falls into the same error. He describes the general medical council as a "trade union of the most antisocial type" and as "preventing the public from addressing itself to the task of calling in any unregistered practitioner who is in competition with those on the register, while at the same time allowing the qualification for that register to remain in many respects not merely useless and out of date, but positively poisonous and murderous." Shaw considers the qualification out of date because physicians are not taught what he regards as the wonderful technic of bone-setters, osteopaths and other irregulars. His rôle as a destructive critic, in which he revels, has of course prepared him for this attitude. But as a man of the world, if for no other reason, he should know that neither the general medical council nor laws of this country prevent any one from practicing any art he likes to profess. This is a very free country, and we have nothing corresponding to the French "illegal practice of medicine."

Cancer Research

At a meeting of the general committee of the Imperial Cancer Research Fund, Sir Humphry Rolleston, chairman of the executive committee, reviewed the report on the year's work made by the director, Dr. J. A. Murray, F.R.S. Dr. William Cramer had investigated the influence of innervation on the experimental production of skin cancer by tar. He deprived an area of skin in mice of the nerve supply and then painted it twice weekly until cancer supervened. This occurred only after a longer course of tarring than was necessary in normal animals. Therefore, absence of nerve supply certainly did not predispose to the genesis of cancer, as had been suggested. The nerves grew again into the denervated area, so that the experiment did not give an absolute answer to the question whether, if the renewal of the nerve supply could be prevented, cancer would not be produced at all. Dr. G. M. Findlay made experiments to determine whether it was possible to reproduce in animals the remarkable sequence reported in the human subject from time to time, in which an accidental tar burn had been followed after a short interval by typical progressive carcinoma at the point of injury. A large number of mice received a single application of hot tar on a small area of the back. Slight swelling and reddening of the skin followed but soon subsided. No further change was observed until the lapse of a year, when three mice showed typical cancer at the site of inoculation application. This result is important, as it shows that general intoxication with tar, which has been invoked by many workers as important in the causation of tar cancer, is, to say the least, not essential. Dr. A. M. Begg has made investigations on the Rous fowl sarcoma and the infective lymphosarcoma of the dog. This work took a new orientation since the publication of the work of Dr. W. E. Gye, who is now collaborating informally with Dr. Begg. Dr. Begg's investigations are progressing satisfactorily and, it is hoped, will soon be ready for publication. The important work of Gye and Barnard is calling for the most careful repetition with as many kinds of tumors as possible. This work is now occupying much of the time of the scientific staff of the Cancer Research Fund.

A Postgraduate School for London

It seems as if the difficulties of establishing a postgraduate school in London, against which medical reformers have struggled in vain for many years, will at last be overcome with the aid of the government. Mr. Neville Chamberlain, minister of health, speaking as the chief guest at the annual dinner of the Royal Society of Medicine, said that the establishment of a postgraduate school in London ought to be brought into operation at the earliest possible moment. Many valiant efforts to do something of the kind had been made in the past, but without success. The time, he thought, had come to try again. Perhaps with cooperation between the medical profession and the ministry of health, and with the good will of some of our medical colleagues beyond the seas, it might be possible to put this question on a new footing. He had already been able to secure the assistance of a number of eminent representative physicians and surgeons to serve on a committee over which he was going to preside. He trusted that in the next year or so they might congratulate themselves on the accomplishment of their desires.

The National Collection of Type Cultures

The Medical Research Council has just issued a second edition of the catalogue of the collection maintained at the Lister Institute of Preventive Medicine. More than 2,000 living strains of bacteria and protozoa affecting animals and plants are maintained. In the single year of 1924, more than 4,000 cultures were distributed to workers. The catalogue gives an alphabetical list of these microbes with their sources. For many years the Lister Institute has assisted bacteriologists at home and abroad by maintaining a limited collection of strains. Before the war there was a collection at the Pasteur Institute, Paris, another at Prague and a third in the Museum of Natural History in New York. But these were limited in range. Early in 1920 the Medical Research Council arranged, with the cooperation of the Lister Institute, to expand the collection into its present form, adding, with the assistance of the British Mycological Society, type cultures of fungi. It is now becoming possible for any research worker, health officer, or the scientific adviser to any industry, to obtain authentic living cultures of most of the living strains of microbes to compare with the organism with which he is working. The collection contains thirty living species of the genus *Aspergillus.* There are examples from soy products used in making pickles in China, from the dust of the London tube railways, from the mealy bug of the sugar cane and from many wild animals in the London zoo. Of the tubercle bacillus there are more than twenty strains—from human cases of lupus, bovine types, avian types, one from a kangaroo, and cold-blooded types from alligators, tortoises, frogs and fishes. There is culture of *Bacillus botulinus* obtained from the only outbreak of botulism that has occurred in this country (in Scotland in 1922). There are examples of the organisms of trypanosomiasis and of nagana disease in tropical Africa.

Conjugal Neurosyphilis and Its Pathogenesis

M. Sézary, in a recent article, calls attention to conjugal neurosyphilis. In such cases both husband and wife are affected with hidden or unrecognized syphilis and present at the same time or successively signs of a nervous affection either parenchymatous (tabes, general paralysis), arterial (hemiplegia, paraplegia) or meningeal (jacksonian epilepsy, paralysis of the cranial nerves). While such cases are not frequent, they are important. Conjugal neurosyphilis constitutes one of the strongest arguments for belief in the neurotropic strain of spirochete. This theory, supported by some authors, is far from being accepted by all neurologists and syphilologists. The fact is, it is exceedingly rare for syphilis in husband and wife to manifest itself exclusively by nervous lesions; frequently one or even both are affected, at the same time that the nervous affection appears, by a characteristic syphilitic aortitis, leukoplakia or gummatous or papulotuberculous cutaneous lesions.

In further support of the belief in the neurotropic strain of spirochete, it has been noted that the offspring of a parent or parents with neurosyphilis has contracted the disease. Such cases are rare, and in some cases the child of such parents is affected with syphilis of the skin or bones. The existence of a strain exclusively neurotropic is, therefore, contradicted by the observed facts. Hereditary predisposition seems to be present in certain cases in which neurosyphilis develops in various members of the same family, contaminated by different sources. It has never been proved that the husband and wife affected by neurosyphilis came from families in which such predisposition existed; furthermore, the part played by hereditary or familial predisposition in the etiology of nervous diseases has been exaggerated.

As to environment, frequently the two partners to the marriage have occupations so widely different that the vulnerability of their nervous system cannot be explained in this way. The alleged effect of conjugal alcoholism is not plausible; the supposed favorable action of alcoholism on neurosyphilis has, moreover, been contested by numerous authors. The social factor plays no part; persons affected with neurosyphilis belong to all classes of society. Nor can inadequate treatment explain conjugal neurosyphilis. No doubt inadequate treatment favors its development, but there is no apparent reason why neurosyphilis should be found in syphilitic married couples who have received inadequate treatment rather than aortic syphilis or syphilis of the skin and bones.

According to Sézary, the pathogenesis of conjugal neurosyphilis will be readily understood by taking in account two factors: (1) the relative rarity of conjugal neurosyphilis, and (2) the fact that if one discriminates between neurosyphilis proper (tabes, general paralysis) and arterial and meningeal neurosyphilis, which are only special types of vascular or other forms of syphilis, it will be seen that the cases of conjugal neurosyphilis proper are rare. For instance, Marie and Beaussart were able to collect during a five-year period, in the large Villejuif psychopathic hospital, only twenty-six cases of conjugal neurosyphilis proper. Neurosyphilis, however, has wide incidence. From observations of patients in the Charité Hospital, Sézary concludes that in old cases of syphilis the manifestations are nervous in two out of three cases. Under these circumstances, there is no need to explain neurosyphilis by neurotropism of the spirochete or predisposition of the patient. It is not surprising that syphilis expresses itself in husband and wife by its most frequent manifestation.

Nontuberculous, Tracheobronchial Adenopathy

Guinon and Levesque, endeavoring to establish more definite criteria for the diagnosis of tuberculous juxtamediastinal lesions, have sought to discover what roentgenologic images represent bronchopulmonary sequelae of acute respiratory diseases. Their results appear in an article in the *Archives de médecine des enfants.* Selecting from patients with tardy respiratory sequelae of infectious diseases (pertussis, measles, acute bronchopneumonia) those who were free from tuberculosis, they found either (1) the absence of all roentgenologic anomalies or (2) quite frequently a roentgenologic image of great diagnostic value. This image is juxtamediastinal but always in the lower half of the thorax, to the right, along the right border of the heart. The image always occupies the space just above the diaphragm, usually extending to it, and lies below the normal bronchovascular shadow. There is never a roentgenologic anomaly along the trachea or at the level of the hilum. It is not a round shadow with clear outlines, but shows lightly shaded bands lengthened obliquely at the base and forming a triangle with the diaphragm as the base, more or less divided, like the jaws of forceps, at the apex of the hilum. Sometimes the external margin of the principal mass sends out horizontal prolongations toward the costal wall. These images show great mobility from coughing or respiration. Finally, the diaphragm is often misshapen; during respiration, it presents the festoon sign described by Maingot. The authors conclude that these images are not indicative of adenopathy and that everything points to their parenchymatous origin. This, together with the ordinary bronchopulmonary syndrome, leads them to think that the respiratory sequelae of infectious diseases consist of various parenchymatous lesions ranging from chronic bronchopneumonia, probably the cause of the roentgenologic modifications previously cited, to the main syndrome of bronchopneumonia with dilatation of the bronchi. Nontuberculous chronic adenopathy never appears, provided the examination is made immediately after convalescence from the acute stage. It is therefore very easy to distinguish the roentgenologic images described above from tuberculous juxtamediastinal images. The latter are located at the hilum, in the angle which the large vessels of the base form with the heart, or at the borders of the trachea. They have a rounded aspect, with frank outlines which point to adenopathy even when they are located in the lower part of the thorax on either side of the heart; one should not confuse them with the special roentgenographic image described above.

PRAGUE

(From Our Regular Correspondent)

Oct. 21, 1925.

Public Health and the Budget

The parliament has just approved the state budget of the ministry of health for 1926. Because the Czechoslovak currency has been stabilized for three years, it is possible to compare the budgets for those years. While the budget for 1925 amounted roughly to 126 million Czechoslovak crowns, the total for 1926 is 146 millions. There are no radical changes in the budget for the next year. The law on the restriction of state personnel prescribed a reduction of 10 per cent. in the personnel of all branches of public service, but it has been decided that the health service shall be reduced only 4 per cent. The largest item in the budget, 39 millions, is for state institutions, including hospitals and state laboratories. The second largest item, 31 millions, is for salaries of health officers. The third largest item, 10 millions, is to maintain indigent patients in public hospitals. Eight millions is appropriated for the fight against such diseases as tuberculosis and venereal diseases. Four millions goes to child welfare, 5 millions for the improvement of public water supplies and sewage disposal plants, and 2½ millions for the construction of hospitals. The health service for the autonomous territory of Carpathian Russia has a special chapter with 11½ millions. While the Czechoslovak crown is valued at 34 crowns to one American dollar, this makes an expenditure of about 30 cents per head for public health purposes.

New School for Social and Public Health Workers

A new school for public health visitors has been opened in Turocz Szt. Marton, Slovakia. The school was organized by the Czechoslovak Red Cross and has been taken over by the county authorities. It is located provisionally in a summer hotel but is to be moved next semester into a new building which is nearly completed. There has long been a need for such a school because Slovakia had no qualified workers in the field of social work and public health. Forty Slovakian girls, all graduates of the domestic science schools, have been accepted for a two years' training. Besides instruction in the theory of social work and public health, they will receive practical training in home visiting. The hospital is not yet big enough to give them the bedside training necessary to qualify them as public health nurses. The practical training will be in the hands of a graduate nurse who has had the international course in public health nursing given under the auspices of the League of Red Cross Societies in England. It is planned to organize in the district in which the school is located a public health demonstration in which the county, the province and the state shall participate and which shall be in charge of a full-time health officer. The idea is to show the girls how a modern health service should be organized so that they may imitate it when they go out into practical life. It is intended to use the same district for the practical training of health officers. Their theoretical preparation is to be given in the state institute of hygiene in Prague, but they must produce evidence that they have undergone practical training in a demonstration district before they may be admitted to final examination.

Orthopedic Congress

The first congress of the Czechoslovak Orthopedic Society, successfully organized by Professor V. Chlumsky, was held in Bratislava, September 27 and 28. More than 150 guests participated. In addition to all three medical faculties of the Czechoslovak Republic, the Polish surgeons and the Jugoslavian medical profession were represented, Professor Lesniowsky coming from Warsaw and Dr. Grospic from Jugoslavia. Professor Chlumsky, who is the chief of the orthopedic clinic at the Bratislava Medical School, was in the chair. He presented a paper on the causes and the modern treatment of incipient scoliosis. Other papers deserving special mention are: the lecture of Professor Tobiasek of Prague on orthopedic gymnastics and their relation to the different systems of physical education; the paper of Dr. Zahradnicek of Brno on the clinical significance of the numerical and morphologic anomalies of the vertebrae, and a lecture of Dr. Burian on plastic operations on the face and extremities. Several resolutions were adopted by the congress. One recommends improvement of the orthopedics branch of medical education by devoting one of the four compulsory semesters in surgery to orthopedics. Another one asks for independent chairs and departments of orthopedics such as have been created in Bratislava with Professor Chlumsky as the chief. This change has brought about a remarkable development of orthopedic service in the Bratislava Medical School. The department should be charged with educating makers of orthopedic appliances who at present, although they have no special education, often advise the public as to the apparatus to be applied and consequently do much harm in many cases. The application of orthopedic procedures should be reserved strictly for specialists, who should be qualified medical practitioners with special postgraduate training in orthopedic clinics.

Operation for Cerebellar Tumor

Professor Schloffer and Professor Poetzl of the Prague German Medical Faculty have recently reported a unique operation, which has been successfully performed. The diagnosis of tumor in the cerebellum was made on a man, aged 40. Because the condition of the patient grew steadily worse, operation was decided on. The operation disclosed a tumor in the right half of the cerebellum and made necessary the removal of almost the whole of this portion of the cerebellum. Fifteen days after the operation the patient was able to leave his bed, and ultimately he returned to his normal occupation. Although he has been under observation for several months, he is feeling well and continues in his previous occupation. The scientific literature contains one case of a similar operation, which was performed by de Stella, whose patient survived the operation but died eight weeks later. Professor Schloffer believes that the beneficial result of his operation is due to the fact that he succeeded in preserving the nucleus dentatus and the whole system of cerebrifugal connections.

Retirement of Professor Jaksch Wartenhorst

Professor Rudolph Jaksch Wartenhorst is retiring as chief of clinic for internal medicine of the Prague German Medical Faculty. He was born in 1855, the son of the famous internist, who was also professor of internal medicine in Prague. After his studies under Klebs, Nothnagel and Przibram in 1883 he became lecturer on internal medicine at the German Medical Faculty in Prague, where he has remained ever since. In 1888 he was appointed professor of internal medicine and developed into the foremost figure of the teaching staff of his institution. His publications are concerned chiefly with metabolic diseases as evidenced in the components of the urine. In the early nineties he initiated the campaign against tuberculosis in Bohemia. In 1893 he founded the German Association for the Erection of Tuberculosis Sanatoriums in Bohemia. In 1903 he transformed the association into a society for aid to the tuberculous, enlarging at the same time the whole scope of the antituberculosis campaign by including in its program especially the erection of antituberculosis dispensaries. Since 1922 he has been the head of the German Federation of Antituberculosis Associations in the Czechoslovak Republic. Professor Eppinger, who has been occupying the chair of internal medicine at the Medical Faculty in Vienna, has been appointed as the successor of Professor Jaksch. Professor Eppinger will begin his lectures in Prague in the summer semester of 1926.

Meeting of Surgicogynecologic Society

The meeting of the Czechoslovak Surgicogynecologic Society was devoted to discussion of the proposal made by its late president, Professor Kukula, shortly before his death. Professor Kukula suffered from angina pectoris, to which he ultimately succumbed. In the last months of his life he paid especial attention to the study of angina pectoris and its treatment. It was shown at his clinic that cervical sympathectomy brings relief in from 60 to 70 per cent. of cases but is often followed by undesired after-effects, such as hemorrhagic pleural effusion, irregularities of deglutition and irritation of the third branch of the trigeminal nerve. All these complications Dr. Jirasek, formerly Dr. Kukula's assistant, attributes to the mechanical irritation of the upper portions of the sympathetic. In order to obviate these complications, Professor Kukula proposed resection of the sympathetic plexus around the aorta. The anatomic possibility of this operation was studied by Dr. C. H. Weigner, professor of surgical anatomy at Prague. He believes that it would be possible to resect the branches of the sympathetic in the anterior mediastinum along the large blood vessels. This operation would have the advantage of avoiding undesirable by-effects. The members of the Surgicogynecologic Society think that the project has been studied so far that it deserves a trial in an actual case with a chance of success.

Changes in Czech Medical Faculty in Prague

Two important changes have occurred recently in the teaching staff of the Czech Medical Faculty in Prague. The chair of pathologic anatomy, after the late Professor Hlava, was given to Prof. Rudolph Kimla. Professor Kimla is the oldest pupil of Hlava, and has been professor of experimental pathology in Prague. In his opening lecture he described his own scientific development by following the history of modern pathologic anatomy. The macroscopic stage of the science was followed by intensive microscopic research and was intensified by the discoveries of Koch and Pasteur. Coordination of these activities showed that mere morphology could not explain all the problems under discussion and therefore it was necessary to pay attention also to the study of pathology. After the World War, social problems began to influence research in theoretical sciences, and international machinery was created for the coordination of research, such as the Health Committee of the League of Nations. Professor Kimla could follow this development on his favored subject, which is primary infection in tuberculosis. According to him, human knowledge can be enlarged only through cooperative research. Prof. A. Ostrcil has been appointed to the chair of gynecology, succeeding Prof. V. Rubeska. Professor Ostrcil has been chief of the gynecologic clinic at the Brno Medical School. In his opening lecture, Professor Ostrcil described the importance of the work of his predecessor for the development of operative gynecology and emphasized the fact that the specialty of gynecology must be built on a fundamental and thorough education in general medicine.

Physical Development of School Children in 1924

Prof. Rudolf Martin of Munich (recently deceased) has given the results of his somatometric and somatoscopic researches on 7,065 children—3,573 boys and 3,492 girls—attending the public schools of Munich. Since 1921, the children of the same seventeen schools have been subjected to regular yearly examinations. The number of children examined in the various age-groups (with the exception of the 10½ age-group) is so large that the averages are reliable. Twenty-one body measurements were made on each child, from which further values were computed. Six descriptive characters were noted in each child and any peculiarities were recorded. Martin sought to establish to what extent the influence of the recent war could be observed in the physical development of our youth. The various age-groups were subjected to these damaging influences varying periods of time; nor were the various war and postwar years equally harmful in their effects on child life. The worst years were those of the food blockade and the year 1923, which witnessed the climax of inflated currency. In these years many parents were unable to secure for their children a sufficient quantity of even the most essential foods. A good deal depends, too, on what stage of physical development the children had reached when their bodies were deprived of foodstuffs that constituted the building material for their normal future development. In 1923, in children that were born during the first years of the war and were thus subjected throughout their early childhood to the damaging influences of poor food, a distinct decline in almost all body measurements, as compared with the physical development recorded in 1921, was noted. Not only were measurements taken, but the general state of nutrition was inspected, the same method being followed that the Quakers used in the medical examinations made in connection with the feeding of German children. An average nutrition was the state most commonly found in all age-groups and both sexes, and the proportion fluctuated between 39.5 and 54.3 per cent. Thirteen per cent. of the children were found to be "badly" or "very badly" nourished. More of the boys were found in the group nourished below the average and more of the girls in the group nourished above the average. Measurements of the girls from 6 to 10 years old showed more subcutaneous fat and more rotundity of the female figure.

The boys were, on the average, taller than the girls. The half-year gains in height corresponded to normal rates of increase. Boys weighed more until the tenth year, when a gradual reversal took place. The chest girth (taken after exhalation) was much less in the girls than in the boys, even with increasing age. Chest girth increased more slowly than height; the relative chest girth dropped from 50.9 in boys aged 6 to 49 in boys aged 9½, after which it began slowly to increase. The corresponding decrease in the girls was from 49.8 to 47.7. Taken absolutely and also in relation to height, the trunk length increased in the two sexes quite uniformly. Not until the seventh year did the growth become more rapid. Until the tenth year was reached, trunk length in the girls, taken absolutely and also in comparison with the height, was less than that of the boys. The relative trunk length dropped continuously from 55 to 54 in the boys, and from 55.6 to 53.7 in the girls. With the length of the legs it was just the opposite. The leg length increased much more rapidly than the trunk length. In boys the increase in leg length between the ages of 6 and 10½ was 11.2 cm.; in girls the increase was 12.5 cm., as compared with an increase in trunk length, during the corresponding period, of only 7.1 and 7.8 cm., respectively. It was evident, therefore, that, in the girls as well, the absolute and the relative values of leg length were greater than in the boys. On the other hand, up to the tenth year, the breadth across the shoulders and the width of the pelvis were almost equal in the two sexes. The typically feminine breadth of trunk does not develop, therefore, until at a later age.

The past year has brought an improvement in the growth of school children of the ages 6 to 10, especially in height and weight. In the children aged 8½, there was an increase of 3.2 cm. in the boys and 2.8 cm. in the girls. In the younger age-groups, though not in the older, the values recorded in 1921 have again been reached. The absolute and relative changes of chest girth in the various age-groups were slight.

Body Build and Physiognomy

Before the Berliner Physiognomische Studiengesellschaft, Dr. Löwenstein, neurologist of Hanover, spoke recently on body build and physiognomy. With the aid of numerous diagrams and portraits, and taking the researches of Professor Kretschmer of Tübingen as a basis, he explained the connection between the body build and the symptoms of mental disturbance, decay and degeneration. In the study of abnormal mental manifestations, psychiatrists no longer confine their observations to the brain and skull formation. On the contrary, in connection with endosecretory processes, the form and structure of the whole body are studied (of which the face may possibly be taken as merely a symptomatic portion). Kretschmer distinguished three different types of body build: (1) the leptosarks, or the slender, usually having a small head, a slender neck and a sunken chest; (2) the athletes, with broad chest and marked muscular development, and (3) the pycnics, or thick-set, with compact body build, short legs, protruding paunch, head thrown forward, a rounded back and usually a heavy beard. The leptosarks and the athletes, if they become affected with mental disease, present the same symptoms, because they have fundamentally the same temperament. Fully developed mental disease in these first two groups affects the intellectual centers; for thinking and feeling are disturbed and their relations to the external world are much affected. Opposed to these two groups (termed schizoids) is the third group, the pycnics, in whom, as a rule, only periodic depression occurs, which does not affect the intellectual centers or relations with the external world. One can observe a temperamental character even in subjects who are mentally sound. For example, Gottfried Keller, Fritz Reuter, H. Seidel, Luther, Blücher, and, among the artists, Thoma and Hals, presented a typically pycnic body build, and their published works give evidence of the corresponding mental temperament. While not naturally given to systematic, logical thinking, there is a vein of humor pervading their works; they have a preference for long-drawn-out epical style and give evidence of an altruistic character. On the other hand, the schizoids (the slender and the athletic types) seek retirement; their acts are usually characterized by pronounced egoism, by reason of which their own personality becomes the center of every interest. They are the great systematic thinkers. We may mention Kant, Newton, Spinoza, Rousseau, Calvin, Schiller, Körner, Feuerbach, Michelangelo and, finally, Strindberg, whose mental affection was of a marked schizophrenic type.

Marriages

Albert C. Van Reenen, Covington, Va., to Miss Gladys Camillia Vermillera of Richmond, October 28.

William Edward Smith to Miss Mary Elizabeth Berkeley Moring, both of Farmville, Va., October 22.

Bolling Jones Atkinson to Miss Eugenia Clementine Vincent, both of Emporia, Va., October 31.

Victor Mackay Daly to Mrs. Anna Raymond, both of Pontiac, Ill., at St. Paul, September 16.

Robert Burwell Groves, Lowell, N. C., to Miss Moody Schools of Richmond, Va., October 10.

Robert Matthews, Norfolk, Va., to Miss Mary Willis McLemore of Suffolk, October 24.

Richard E. Shope, Iowa City, to Miss Helen Ellis of Linville, at Des Moines, recently.

Beverley F. Eckles to Miss Annie Gill Dixon, both of Richmond, Va., October 31.

Ernest L. Coffin, St. Louis, to Miss J. Rebecca Jarvis of Webster Groves, October 3.

Donald E. Bell, Newcastle, Ind., to Miss Margaret Benoy of Indianapolis, recently.

Deaths

John Lewis Hildreth, Winchester, Mass.; Dartmouth Medical School, Hanover, 1868; member of the Massachusetts Medical Society; emeritus professor of clinical medicine, and formerly dean, Tufts College Medical School, Boston; at one time member of the Cambridge (Mass.) School Board, and on the staff of the Cambridge Hospital; member of the Massachusetts State Board of Lunacy and Charity, 1895-1898; aged 87; died, November 27.

Thomas Roy Martin ⊕ Duluth, Minn.; University of Minnesota Medical School, Minneapolis, 1907; formerly demonstrator of pathology and bacteriology at his alma mater; past president of the St. Louis County Medical Society; member of the Minnesota Pathological Society, the American College of Physcians, and the Radiological Society of North America; aged 43; died, November 15.

Thomas Grant Alcorn, Thompsonville, Conn.; College of Physicians and Surgeons, Boston, 1898; member of the Connecticut State Medical Society; past president of the Hartford County Medical Society; formerly state senator; aged 56; died suddenly, November 27, of cerebral hemorrhage.

Romulus Armfield, Marshville, N. C.; Medical College of Virginia, Richmond, 1881; member of the Medical Society of the State of North Carolina; past president of the Union Medical Society; aged 73; died, November 23, at the Ellen Fitzgerald Hospital, Monroe, of chronic nephritis.

George Albert Fuson, Everett, Wash.; Barnes Medical College, St. Louis, 1899; member of the Washington State Medical Association; formerly health officer of Cascade County (Mont.), and president of the Montana Public Health Association; aged 54; died in November.

William Allison Secrist, Alpena, Mich.; Starling Medical College, Columbus, 1881; member of the Michigan State Medical Society; past president of the Alpena County Medical Society; aged 72; died, November 18, of cerebral hemorrhage.

George Theophilus Kemp, Baltimore; Long Island College Hospital, Brooklyn, 1891; formerly professor of physiology, College of Physicians and Surgeons, Chicago; aged 64; died, November 24, at the Church Home and Infirmary, of pneumonia.

L. Cooper Harman, Philipsburg, Pa.; Jefferson Medical College of Philadelphia, 1882; member of the Medical Society of the State of Pennsylvania; aged 64; died, September 13, of lung abscess and pneumonia, following an operation for gallstones.

George Eugene Harbert ⊕ Beverly, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1899; aged 50; died, November 12, at the University of Pennsylvania Hospital, Philadelphia, of injuries received in an automobile accident.

Charles M. Moates, Leavenworth, Kan.; Meharry Medical College, Nashville, Tenn., 1888; member of the Kansas Medical Society; formerly city physician; aged 63; died, November 17, at St. John's Hospital, of pneumonia.

Richard Joseph Dwyer ⊕ Hartford, Conn.; Jefferson Medical College of Philadelphia, 1908; served in the M. C., U. S. Army, during the World War, with the rank of captain; aged 48; died, October 22, of pneumonia.

Christian Martin Berntsen, Chicago; Northwestern University Medical School, Chicago, 1908; member of the Illinois State Medical Society; aged 41; died, November 28, of bronchopneumonia, following influenza.

Herbert Houston Sawyer, Boston; Boston University School of Medicine, 1893; member of the Massachusetts Medical Society, and the New England Dermatological Society; aged 55; died, November 13.

Ovid V. Burnett, Shelton Laurel, N. C.; Hospital College of Medicine, Medical Department Central University of Kentucky, Louisville, 1904; aged 50; was shot and killed, November 16.

Jedediah Kilbourne Hayward, New York; Bellevue Hospital Medical College, New York, 1893; aged 54; died, November 15, at the Manhattan State Hospital, of acute myocarditis.

Frank Henry Zitz, New York; Medical Department of Columbia College, New York, 1888; member of the Medical Society of the State of New York; aged 61; died, November 26.

Frances Alice Harper ⊕ Pittsburgh, Kan.; Kansas Medical College, Topeka, 1904; aged 54; died, September 15, at the Mount Carmel Hospital, of cerebral hemorrhage.

Andrew Johnson Baird, Gatesville, Texas; Vanderbilt University Medical Department, Nashville, Tenn., 1879; aged 70; died, November 5, of cardiovascular disease.

Jesse David Moore, New Castle, Pa.; Medical Department of the University of the City of New York, 1885; aged 66; died, November 14, of cerebral hemorrhage.

James M. Boyd, Annapolis, Ind.; University of Pennsylvania School of Medicine, Philadelphia, 1877; aged 78; died, November 16, of heart disease.

James Wales Henry, Jackson, Ohio; Miami Medical College, Cincinnati, 1884; formerly a druggist; aged 85; died, November 22, at Columbus.

Daniel W. Carlisle, Princeton, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1865; aged 87; died, October 30, following a long illness.

Samuel Cecil Oglesby, Girdletree, Md.; University of Maryland School of Medicine, 1892; aged 55; died, November 15, of bronchial asthma.

William De Caux Tilney, Crawfordsville, Ind.; Philadelphia University of Medicine and Surgery, Philadelphia, 1878; aged 84; died, October 11.

Thomas Wisdom Repass, Wytheville, Va.; Medical College of Virginia, Richmond, 1895; aged 58; died, November 8, of cerebral hemorrhage.

Granville H. Albright, Barbourville, Ky.; University of Louisville School of Medicine, 1892; also a druggist; aged 69; died, November 13.

Edward Rushmore, Plainfield, N. J.; Jefferson Medical College of Philadelphia, 1872; aged 80; died, November 24, of pneumonia.

Frank E. Morley ⊕ Viroqua, Wis.; Rush Medical College, Chicago, 1893; aged 63; died, November 21, of cerebral hemorrhage.

Walter Henry Kelley, Boston; Medical School of Harvard University, Boston, 1902; aged 54; died, November 16, of pneumonia.

Jefferson Pugh, Greensburg, Ind.; Indiana Medical College, Indianapolis, 1874; died, September 26, of chronic nephritis.

Charles Thomas McClane, Roswell, N. M.; Eclectic Medical Institute, Cincinnati, 1878; aged 80; died, October 20.

Alphonsus J. Forget, Los Angeles; Catholic University, Louvain, Belgium, 1894; aged 66; died, November 13.

Garrett Pigman, Liberty, Ind.; Bellevue Hospital Medical College, New York, 1883; aged 67; died, October 17.

John Newton Ryan, Coyle, Okla. (licensed, Oklahoma, under the Act of 1908); aged 73; died, November 8.

Anthony Doyle, New Canton, Ill.; American Medical College, St. Louis, 1887; aged 93; died, November 5.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

INCITAMIN NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. Puckner, Secretary.

Incitamin was presented for consideration by Lehn & Fink, Inc., New York, with the statement that it is manufactured by A. H. Riise, Copenhagen, Denmark. In the information furnished the Council it was stated that Incitamin is a "standardized preparation of equine saliva, freed of coagulable substances," that "each cubic centimeter contains 12 units of Ptyalin" (the unit is defined and a method for testing given), that it is preserved with 1 per cent. of chinosol. It was stated to be indicated in the treatment of indolent ulcers.

> "According to the theory of the originators, Incitamin owes its therapeutic value to the stimulation of the activity of the blood plasma."

Entirely different statements as to the composition are made on the trade package and the advertising which was submitted. Here it is stated:

> "Incitamin is a mixture containing saliva (equine), serum (also equine), and pancreatic extract. . . . It is preserved by the addition of one-half of one per cent. of phenol."

The Council called the attention of Lehn & Fink, Inc., to the contradictions in the statement of composition and pointed out that no pharmacologic data of any kind was given indicating that such a preparation is useful and that no clinical evidence had been presented for its clinical usefulness. The firm was informed that Incitamin could not be considered on the data as to composition and action which had been submitted.

After the Council had postponed the consideration of Incitamin for more than ten months, Lehn & Fink, Inc., submitted further information. This consisted of a report that 6 c.c. of Incitamin per kilogram was not fatal to guinea-pigs when injected subcutaneously, and photostatic copies of a number of reports from physicians who had used the preparation. No further information was furnished in regard to the composition.

The reports from physicians are, for the most part, based on single cases of various forms of ulcers. A considerable number of the reports are to the effect that the result was "good" or "very good" or "favorable." Other reports state "improvement" or "promising"; others state that the results were "indefinite," "rather slow," "doubtful," "cannot see any marked change," "not satisfactory," etc. In some of the cases in which improvement was noted, other forms of treatment were also used. In other cases, Incitamin was used after various kinds—in some cases rather drastic kinds—of treatment had been employed and the suspicion arises that the favorable course of the case following the use of Incitamin was due to the cessation of harmful treatment. There is nothing in the case reports to suggest that better results were obtained by the use of Incitamin than can be obtained by the use of ordinary methods, or that equally good results could not be obtained with 0.5 per cent. phenol solution.

The Council found Incitamin unacceptable for New and Nonofficial Remedies because the statements of composition are contradictory; no data are given as to the amount of equine serum and pancreatic extract present; no data of any kind are given that the ingredients (whatever they are) have any action (except perhaps the phenol or chinosol); and so far as the evidence goes, it is an absurd and unscientific mixture.

When the preceding statement was sent to Lehn & Fink, Inc., the firm replied that Incitamin formerly contained "saliva, equine serum and pancreatic extract," but that the formula had been changed to a "standardized preparation of equine saliva." The firm also requested opportunity to submit further evidence. The Council, therefore, postponed publication of its report for more than six months. During this period no further evidence for the usefulness of Incitamin was received: therefore, the Council authorized publication of this report.

MORE MISBRANDED NOSTRUMS

Abstracts of Recent Notices of Judgment Issued by the Bureau of Chemistry of the United States Department of Agriculture

Gary's Vegetable Ointment.—The Sloan and Spencer Medicine Co., Birmingham, Ala., are alleged to have shipped in February, May, July and October, 1923, respectively, a quantity of "Dr. Gray's (Gary's) Vegetable Ointment" from Alabama to Mississippi. The Bureau of Chemistry reported that analysis showed the product to consist of two liquids that would not mix, the lighter being mainly kerosene and the heavier alcohol; both contained turpentine oil, camphor, and menthol. The product was declared misbranded, first, because it was not an ointment, and, second, because ridiculously false and fraudulent therapeutic claims were made for it, the stuff being recommended for practically all the ailments known to the human system. In April, 1924, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment No. 13080; issued May, 1925.*]

The files of the Bureau of Investigation show that "Dr. Gary's Vegetable Ointment" used to be manufactured by "Dr. P. Gary" of Chattanooga, Tenn. Gary, so far as the records show, never was a physician. In 1919, the city of Cleveland, Ohio, prohibited the sale of Gary's Vegetable Ointment, manufactured at that time by the Gary Medicine Company of Chattanooga. The Chattanooga *Times* for Nov. 22, 1919, reported that two of the three partners in the Dr. Gary's Medicine Company of that city had filed suit against "Dr." Presley Gary, praying the appointment of a receiver for the company and an injunction restraining Gary from disposing of any of the property owned by the partnership. Further, the paper reported: "According to the allegations of the bill, Dr. Gary has lately taken to drink and has appropriated much of the alcohol used in the manufacture of his 'Vegetable Ointment' to satisfy his own appetite"; also, according to the same bill, Gary had often promised either to stop drinking or withdraw from the partnership, but had done neither. It was charged, too, that Gary had sold thirty-five hundred bottles of this fraudulent nostrum that should have netted the partnership about $1,750, of which the two complaining partners got only $190.

Sayman's Wonder Herbs.—The T. M. Sayman Products Co., St. Louis, Mo., shipped in January, 1924, to the state of Kansas a quantity of "Dr. Sayman's Wonder Herbs," which the government declared misbranded. Analysis of a sample of the article by the Bureau of Chemistry showed it to consist essentially of a mixture of baking soda, powdered ginger, gentian, rhubarb, licorice, cascara sagrada, buchu, senna, mandrake and buckthorn. The stuff was declared misbranded, first, because it was said to be composed of "all herbs"; as baking soda is not an herb this was a falsehood. It was further declared misbranded because the claim that it would regulate the liver, kidneys, cleanse the blood, aid digestion, cure nervousness, syphilis, female complaints and various other conditions as false and fraudulent. In January, 1925, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed.—[*Notice of Judgment No. 13098; issued May, 1925.*]

Chappelear's Bronchini.—William M. Chappelear & Sons Co., Zanesville, Ohio, are alleged to have shipped in various consignments in November, 1923, and May, June and October, 1924, respectively, a quantity of "Chappelear's Bronchini," which was declared misbranded. When analyzed in the

Bureau of Chemistry it was reported to consist of ammonium chlorid, extracts of plant drugs, flavoring material, including anise and sassafras oils, sugar, alcohol, and water. The stuff was sold as an alleged cure for bronchitis, asthma, croup, influenza, and "throat and lung troubles." The claims were declared false and fraudulent. Furthermore, while the label declared the presence of 40 per cent. alcohol, there was only about 30 per cent. present. In April, 1925, the William M. Chappelear & Sons Co., having admitted the allegations, decrees of condemnation and forfeiture were entered and the court ordered that the product be released to the concern on payment of the cost and execution of a bond of $1,500 conditioned in part that the preparation be relabeled under the supervision of the Department of Agriculture.—[*Notice of Judgment No. 13365; issued August, 1925.*]

S-K Remedy.—The S-K Remedy Co., Oakland, Oregon, are alleged to have shipped to California in September, 1920, a quantity of "S-K Remedy" which was declared misbranded. The Bureau of Chemistry reported that analysis showed the product to be composed essentially of vegetable drugs including aloes and a small quantity of a mydriatic alkaloid, alcohol and water. Some of the claims made for this product were:

> "This new and wonderful Remedy known as S-K Sifkure is the first and only purely vegetable compound ever produced that has stood the test as a remedy for Syphilis. S-K is not an experiment, it has passed through that stage. Fifteen years of constant use on hundreds and hundreds of cases has as yet to produce a single case of syphilis that failed to yield to the S-K treatment."

These vicious claims were naturally declared false and fraudulent, and in January, 1925, judgment of condemnation and forfeiture was entered and the court ordered the product to be destroyed.—[*Notice of Judgment No. 13239; issued June, 1925.*]

Correspondence

"ACHLORHYDRIA PRECEDING PERNICIOUS ANEMIA"

To the Editor:—I have read (THE JOURNAL, November 21, p. 1638) the report of a case of achlorhydria preceding pernicious anemia in which the achlorhydria had existed for fourteen years previous to the development of the anemia. I can report one case of pernicious anemia in which the achlorhydria was present twenty-five years before the appearance of symptoms of pernicious anemia. In this case the pernicious anemia developed and progressed, with clinical signs and symptoms of an organic lesion of the spinal cord, namely, so-called subacute combined sclerosis of the spinal cord, which is present in a large percentage of cases of pernicious anemia. This patient developed pernicious anemia with all its usual signs and symptoms, and the achlorhydria was present twenty-five years before the appearance of the anemia, as shown by analysis of the gastric contents.

In another case, a woman had achlorhydria twenty years previous to the appearance of symptoms of pernicious anemia. I have had under observation a large number of cases in which we have observed achlorhydria eight and ten years previous to the appearance of anemia, and still a larger number in which we have been able to observe achlorhydria for a period of four or five years.

In a paper, entitled "A Clinical Study of Two Hundred and Sixty-Four Cases of Pernicious Anemia with Special Reference to the Involvement of the Central Nervous System" (*Battle Creek Sanit. & Hosp. Bull.*, April, 1923), I called particular attention to the fact that a condition of achlorhydria or an absence of hydrochloric acid and pepsin in the contents of the gastric juice existed for a period of many years previous to the appearance of any signs of anemia.

The evidence gathered from a study of this large group of cases seems conclusive that all cases of pernicious anemia are preceded by a rather lengthy period of achlorhydria, and in some of these cases, as in the case of a man mentioned above, this period may be at least twenty-five years before any signs of anemia appear. Another important fact in connection with the finding of achlorhydria is that most of these persons have badly infected teeth, pyorrhea alveolaris, and also many of them have infected tonsils. The evidence is quite strong that the achlorhydria and the pernicious anemia that follows or is associated with the achlorhydria are both the result of an infection from the mouth, causing an atrophy of the peptic glands of the stomach and later causing a destruction of the blood cells and pathologic changes in the spinal cord and other parts of the body.

W. H. RILEY, M.D., Battle Creek, Mich.

"SPIROCHETAL PULMONARY GANGRENE TREATED WITH ARSPHENAMINS"

To the Editor:—Through an error, the report of my discussion (THE JOURNAL, November 7, p. 1459) on the article on spirochetal pulmonary gangrene by myself and Dr. Berger was not corrected for publication. Because of the mistakes in that report, I will appreciate it if you publish the following:

In these cases, there is usually a pyorrhea, dental caries or some active lesion in the mouth associated with Vincent organisms. In one case at necropsy a molar tooth was found carious, the cavities filled with foul smelling, greenish material containing many spirochetes. These organisms are best stained by the Fontana silver impregnation method. The predominating organisms in early pulmonary gangrene are of the Vincent type.

Before ulceration occurs, there is usually a peribronchial and peribronchiolar consolidation. Then the lung has a moth-eaten appearance. It is mottled with gray-green, foul smelling areas containing Vincent organisms. Later there are small and large cavities. Unlike those of tuberculosis, there are no ridges or bridges present. The Vincent organisms spare nothing, and shreds only of necrotic tissue are left hanging to the walls of the cavities, which are practically hollow spherical. Still later, the lung will often show healed, healing and active grangrenous lesions. An interesting complication in one case was a brain abscess. The abscess had the brown-greenish-grayish appearance of the lung lesion and with it there were associated a number of spirochetes.

BENJAMIN S. KLINE, M.D., Cleveland.

"MEDICAL HISTORICAL PERSPECTIVE"

To the Editor:—I suspect that more than one teacher of medical students has been somewhat disconcerted after reading the editorial comment on medical historical perspective in THE JOURNAL (November 21, p. 1645). The item details the replies of thirty junior and senior students to an inquiry regarding "the names of five persons who, in their opinion, might be considered as having made the greatest contributions to medical science." The editorial writer, after listing the students' answers, comments: "How many had a clear conception of what constitute contributions to the progress of medical sciences?"

Let us admit frankly at the outset that "the mark of the cultured man in any field is a knowledge of its background and its growth, and of its relation to the rest of the cosmic scheme that we call civilization." In a recently published historical outline, M. G. Seelig (Medicine, Baltimore, Williams and Wilkins Company, 1925) remarked that the opinion of medical educators is unanimous regarding both the practical and the cultural value of the study of the history of medicine. However, the author adds: "Many important considerations militate against the establishment of such a discipline within the formal medical curriculum. Other influences check the initiative of the medical undergraduate who has at least a fleeting independent impulse to acquaint himself with the medical past; for one thing, he shies at the various authoritative books devoted to the history of medicine, frightened by their bulk as contrasted with the small amount of free time at his disposal."

Nor is this the sole limitation to the medical students' proficiency in the history of science. Driven at a frightful pace through the intricate mazes of almost innumerable facts, old and new, he scarcely finds time to catch his breath long enough to marshal his thoughts into orderly sequence. Add to this the multiplicity of details of technic that must likewise be mastered, and the probable place of the history of medicine in the ensemble of a senior, not to say junior, student's studies can be imagined.

After all, enthusiasm for the historical aspects of science grows with maturity, with opportunity for reflection, with a ready familiarity that develops perspective. Are we expecting too much erudition and expertness at a time when the elements of medicine are first being acquired? Culture involves an attitude of mind and a mode of personal reaction far more than it implies the ability to distinguish succinctly the masters of medicine.

Lafayette B. Mendel, New Haven, Conn.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HEALTHFUL VENTILATION

To the Editor:—I am glad to read your editorial "Air Currents in Ventilation." I note that you consider "badness" of air due to chemical change or poisonous organic respiratory products, both as negligible and obsolete factors. *From your article, I am unable to tell whether you lay* stress on a supply of fresh air from outside for your air currents or whether agitation of a given volume of air would fulfil the conditions indefinitely. If the latter, ventilation would be reduced to a liberal supply of electric fans. If the former, do modern experiments require anything like the amount of fresh air that we formerly supposed necessary? Past views of this subject have required a certain number of cubic feet of new air per person per hour in schoolhouses.

Oliver H. Howe, M.D., Cohasset, Mass.

Answer.—In all ventilation problems a distinction should be made between places like private houses, where a few people gather, and public places, such as theaters. In the former, air leakage is so great that it is practically impossible to detect the decrease of oxygen or increase of carbon dioxid due to the respiration of the occupants. The humidity never gets high, and air may be recirculated without danger. Of course, the taking of cold air from outside into the home in cold weather is throwing away coal. Fans would help house comfort, particularly if so arranged as to force out the hot layer next the ceiling and mix it with the cooler air near the floor.

In places where many people gather it is sometimes possible to detect a difference in air gases as compared with outside air, but even in such cases the differences are small and not of physiologic importance. However, in the presence of many people the temperature and humidity of the air become high, and either new air should be freely admitted or else the air of the room should be reconditioned and recirculated. Fans are a help in a crowded room, but may not be sufficient to give comfort. Comfort depends on the ability of the body to lose heat as fast as it is produced. We cannot do that when the surrounding air is too warm and humid.

The usual figures of fresh air requirement are possibly too high. "Keep down the temperature" should be the motto in every school room. Air motion should be sought by fans or other devices, and enough outside air admitted so that comfort is maintained.

A popular article on some of these problems will appear in the January number of *Hygeia* under the title, "How to Put Humidity in Your Home." The spray column humidifier and cooler there described would solve the problem of good air in most school rooms.

It should perhaps be added that air washing may actually diminish the quantity of water in air. If air of high humidity and high temperature is brought in contact with a fine spray of cold water, the air comes out cool and saturated with water vapor. But the total moisture in the air at the lower temperature may be less than that present before it entered the washer. Such air, as it is warmed up in breathing, takes on more water, keeps down body temperature and contributes to comfort.

NEPHRITIN

To the Editor:—May I not acknowledge through The Journal the receipt from Reed and Carnrick of their booklet entitled "The Reserve Wealth of the Kidneys"? It has a nice cover and is well gotten up. It has nice pictures. In it are recorded some known truths about the kidneys and much that may be questioned. Some trite sayings are quoted, such as "The kidney expects every tube to do its duty," and "Don't cross bridges until you come to them."

Then the doctors are joshed: "Some patients first make sure that they have given all advertised remedies a fair trial, then adopt the advice of a neighbor who was 'cured of the same complaint' by a chiropractor, finally appealing to a regular practitioner as a last resort."

Further on, the pamphlet speaks about "setting up a vicious circle," and "when the kidneys go on strike the employees of the Internal Secretion Department walk out in a body," and "should the executive import a slave-driver to lash the loyal tubes on to and beyond their endurance?"

Again: "What glandular therapy does for myxedema, Nephritin will do for Nephritis." Right after this statement are a lot of claims, which I pass by with a question: "Nephritin uses its potency to control and *direct* the natural function of the kidneys." "We can, however, by the use of Nephritin, make every healthy cell do its full duty."

May I ask that you look over the inclosed "booklet" and let your readers have a little light on the subject? Known truth in the matter would be applicable to a purpose.

Victor S. Messinger, M.D., Easton, Pa.

Answer.—The present claims for Nephritin (Reed and Carnrick) appear to be substantially the same as those advanced when the Council declared this preparation, along with other products of this company, inadmissible to New and Nonofficial Remedies ("Reed and Carnrick's Methods," The Journal, Oct. 5, 1907, p. 1198). A summary of the Council's findings on Nephritin was later published in answer to a query (The Journal, April 21, 1923, p. 1167). The Council rejected Nephritin because of the grossly exaggerated, unwarranted and misleading claims made for it by the manufacturers, inviting them at any time to present more and fuller evidence to substantiate the claims. This they have never done, though they continue to circularize the profession with booklets such as the one here mentioned.

DEVICES TO AID HEARING

To the Editor:—I have a patient who has suffered some fifteen years with defective hearing following a double mastoid infection. He requested me to write you for advice as to the best form of apparatus to buy to help his hearing. He has used a Morley and one or two others without much help. He wanted to know about the apparatus the Dictograph people put out or any other that you may be familiar with and can recommend.

J. S. Alford, M.D., Crested Butte, Colo.

Answer.—Small apparatus for insertion in the external auditory canal do not as a rule improve the hearing. Many persons do not wish to carry with them a hearing tube, which, although it is of great assistance, is rather cumbersome and unsightly. The aids to hearing that have given the greatest satisfaction are those which are activated by the electric current. A number of these are on the market, but most of them have the objection that it is necessary to carry a battery on one's person and also a receiver and ear attachment. Most of the electrical apparatus have a good many adventitious noises and are sometimes confusing. In cases of nerve deafness, these appliances are not of much service; but in the one mentioned, in which there has been mastoid involvement and it is the conduction apparatus that is mostly affected, these appliances usually give considerable assistance. During the last few years, besides batteries, several appliances have been evolved that utilize vacuum tube oscillators (the same sort of tubes that are used in radio outfits) for amplifying the sound. There is one called the Vactuphone which is said to give great satisfaction. The Western Electric Company of New York also is perfecting an apparatus of which the ear piece is small or practically invisible, and in which the audion bulb is also used for intensifying the sound. The last two mentioned devices are rather expensive, and it is better to test them out thoroughly on the patient before purchasing. In most of the appliances all the tones are amplified alike, whereas the most desirable form of apparatus which could be had is that in which those particular tones to which the patient is hard of hearing are intensified to the greatest degree.

SMALLPOX VACCINATION

To the Editor—We are having a few smallpox cases here, and I should like to ask some questions that I find unmentioned in my textbooks. Please reply in The Journal 1 After an attack of smallpox (less than six months before), would a vaccination "take"? This patient had an eruptive disease, either chickenpox or variola, but about five or six months later was successfully vaccinated. He had never before been vaccinated. 2. Does variola in a pregnant mother confer any immunity on the fetus? Does it confer any immunity at birth only? 3. If glycerinated vaccine 'dies," when exposed to a temperature much above 40 to 45 F., how is it that "ivory points" of past years, before the glycerin lymph was intro duced (which were never kept in the icebox as the glycerin lymph is directed to be done), were able to inoculate patients? 4. In the case of *two brothers, both healthy, two tubes of vaccine from the same lot and* just off the ice were used; one got a take the first time, yet the other failed to and has twice since What is the cause? Is the second brother immune? Please omit my name

M D, Missouri

Answer.—1. It is not reasonable to expect that a vaccination should take six months after an attack of smallpox, and it is quite certain that the disease the patient had was not smallpox.

2. If a woman suffers from smallpox during pregnancy, it is possible that some immunity may be transferred to the fetus by the passage of antibodies through the placenta. It is also possible that there may occur antibodies in the mother's milk and that the nursling may become passively immunized from this milk. In either case the immunity thus conferred, being passive, will be of comparatively short duration. The possibility should not be overlooked that the fetus may survive an intra-uterine smallpox, which would leave a much more permanent and active immunity

3 Generally speaking, dried biologic products such as vaccine maintain their potency longer than in liquids.

4 It would be a mistake to assume that the brother in whom the vaccination failed is immune to smallpox He should be vaccinated again

DIHYDROXYACETONE

To the Editor.—A newspaper clipping states that dioxyacetone, a new diabetes remedy to reduce sugar, may be taken by mouth instead of by injection One of my patients asks me to find out about it.

J. A. H, New York.

Answer.—Dioxyacetone (better called dihydroxyacetone) was reported on in the *Canadian Medical Association Journal*, April and May, 1925, by I. M. Rabinowitch.

According to Rabinowitch, the acidosis of diabetes was overcome by the administration of dihydroxyacetone

Following is an abstract from Dr. Rabinowitch's first paper:

> Dihydroxyacetone is a ketotriose, unstable in alkaline mediums, readily oxidized, and nontoxic in dosage of 50 to 100 gm by the mouth Its administration is followed by lowering of blood sugar, and it appears to have some influence on the excretion of glucose In one case of diabetes it was found to replace small amounts of insulin, at least temporarily

SMELLS OF THE HUMAN BODY

To the Editor:—Could you furnish me with some references to the subject of smells of the human body? Please omit my name

M D, Philadelphia

Answer.—Following are references to published articles on this subject:

Thomayer, J.: Diagnostic Importance of Smelling, *Cas lek cesk* **62:** 669 (June 23) 1923

ADMINISTRATION OF DIPHTHERIA ANTITOXIN

To the Editor:—Where is the best location to give 1 c c doses of diphtheria toxin antitoxin to school children 6 to 7 years of age? Should these doses be given subcutaneously or intramuscularly?

F L Salisbury, M.D, Cleveland

Answer:—It is customary to give the injections subcutaneously in the outer side of the arm. It probably makes little difference whether the injection is made subcutaneously or intramuscularly.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

Alabama Montgomery, Jan. 12. Chairman, Dr. S. W. Welch, Montgomery.

Arizona. Phoenix, Jan. 5 6. Sec, Dr. W. O. Sweek, 404 Heard Bldg, Phoenix.

Colorado: Denver, Jan. 5. Sec, Dr. David A. Strickler, 612 Empire Bldg, Denver.

District of Columbia: Jan. 12. Sec, Dr. Edgar P. Copeland, Apt. 104, Stoneleigh Court, Washington, D. C.

Hawaii: Honolulu, Jan 11. Sec, Dr. G C. Milnor, 401 So. Beretania St, Honolulu.

Michigan June Examination

Dr Guy L Connor, secretary of the Michigan Board of Registration in Medicine, reports the written examination held at Ann Arbor, June 10-11, 1925. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. One hundred and seventy-five candidates were examined, all of whom passed. The following colleges were represented:

PASSED		
College	Year Grad.	Per Cent.
Northwestern University Medical School	(1925) (1925)*	84, 85 84
Rush Medical College	(1925)*	86
The General Medical College	(1924)	83
University of Illinois.	(1925)	85
Boston University School of Medicine	(1924)	86
Harvard University	(1922) (1924)	85 85
Tufts College Medical School	(1923) (1924)	85 83, 85
University of Michigan Medical School	(1924) (1925)	85 80, 81, 81, 81, 81, 82, 82, 82, 82, 82, 82, 82, 82, 82, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 83, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 85, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 86, 87, 87, 87, 87, 87, 87, 88, 89
University of Virginia Department of Medicine	(1923)	84
McGill University Faculty of Medicine	(1906) (1922) (1923) (1924)	80 85 86 83, 84, 84, 84
University of Toronto Faculty of Medicine	(1919) (1921) (1924)	84 82 82, 83, 84, 85, 86
Western University Faculty of Medicine	(1921) (1922)	83
University of Copenhagen, Denmark.	(1924)†	82

Dr. Connor also reports the written examination held at Detroit, June 15-17, 1925. The examination covered 14 subjects, and included 100 questions. An average of 75 per cent. was required to pass. Ninety-seven candidates took the examination. Eighty-eight, including 18 chiropractors and 1 chiropodist, passed, and 9, including 7 chiropractors, failed. The following colleges were represented:

PASSED		
College	Year Grad.	Per Cent.
Northwestern University Medical School	(1925)	84, 84, 88
Detroit College of Medicine and Surgery	(1925)*	80, 80 8, 81, 81, 81, 81, 81.7, 82, 82 9, 83, 83, 83.2, 83 7, 83.7, 84, 84, 84, 84, 84, 84, 84, 84, 84, 84 2, 84 3, 84 4, 84 5, 85, 85, 85, 85, 85, 85, 85, 85, 85.1, 86, 86, 86, 86, 86, 86, 86, 86.2, 86 3, 86 4, 87, 87, 87

St. Louis University School of Medicine	(1925)	80, 85.9
Queen's University Faculty of Medicine	(1924)	84.3
McGill University Faculty of Medicine	(1924)	86
University of Toronto Faculty of Medicine	(1914)	84, (1920) 84.4, (1921) 85.8, (1923) 83, 86.8, (1924) 83, 83, 83.7, 84, 84.1
University of Göttingen, Germany	(1919)†	79
University of Naples, Italy	(1911)†	76
University of Jurjev, Russia	(1918)†	77

FAILED

College	Year Grad.	Per Cent.
University of Palermo, Italy	(1904)† 43, (1920)†	61

* These candidates have finished their medical course, and will receive their M.D. degrees on completion of a year's internship in a hospital.

† Graduation not directly verified by the American Medical Association.

Book Notices

Studies of Mental Defects and Handicaps. By J. E. Wallace Wallin, Ph.D., Professor of Clinical Psychology, Miami University. Paper. Price, 75 cents. Pp. 177. Oxford, Ohio: Miami University, 1925.

In this bulletin are collected a series of studies on mental deficiency that appeared previously in various periodicals. They represent some of the results of seven years' work of the Psycho-Educational Clinic of the St. Louis public school system, while the author was its director. The studies include not only the results of psychometric tests of children reported by the teachers as deficient, but also the outcome of parallel investigations into heredity, physical health, etiologic factors, scaphoid scapulas, behavior characteristics such as truancy and delinquency, and certain speech and language disorders. It is somewhat unfortunate that the tabulations are given throughout in percentage form without correlations. The material entering into these tables is too extensive for detailed discussion here. The author frankly admits the inadequacy of many of his data, even though he is often dogmatic. He is especially emphatic in regard to the interpretation of age levels as indicators of feeblemindedness. In discussing etiology and the relations with pathologic conditions, he has relied on the reports of others, including medical inspectors of the schools. It is not easy, as the author recognizes, to evaluate many of these data; especially is this true for one who is not fully trained in medicine. This is well shown in the chapter on scaphoid scapulas; the criticisms by the author on the faulty findings of the physicians in such a simple and objective investigation will naturally arouse doubts as to the adequacy of other findings that are used as a basis for conclusions. For example, "infantile paralysis" is accepted as the adequate "sole cause" of mental deficiency in two cases. This use of the term suggests a lay rather than a well informed medical source, but it is accepted without comment. Though the statement is made that medical examinations were performed by school medical inspectors, there is nothing in the text to indicate how they were made or to differentiate what was reported by physicians from that by friends, nurses or others.

The discussion of the value of psychometric tests in diagnosing feeblemindedness, by which is meant social and economic dependence or incompetence due to congenital or early acquired intellectual deficiency, is a good illustration of the pragmatic, social attitude adopted by the author. He points out that many persons testing even so low as 9 years in mental age are quite capable of self support and full social responsibility. This opinion is supported by figures from the army examinations and by the findings from the admittedly inadequate follow-up studies that have been possible since the work with school children in St. Louis was undertaken. He makes no allowance for the fact that in the army the tests were applied to adults. He expresses further the opinion that "the degree of intelligence deficiency necessary to constitute feeblemindedness must be so serious that the individual on attaining his maturity will not exceed an intelligence level of 9 years." The full meaning of this assertion becomes clear from the statement in another chapter that "we cannot adequately diagnose a child's educational or social capacity or prognose his industrial capability by intelligence tests alone." The life history and behavior characteristics must be taken into account: unfortunately, such traits are insusceptible of exact measurement. The conclusions reached, therefore, are in accord with those of the psychiatrist, who regards the mental age as only one factor in a complex picture.

The Missouri law dealing with backward, feebleminded and otherwise handicapped children by establishing special and ungraded classes in the schools is discussed in detail. This will prove of value to all interested in the development of state plans for the care of mental defectives. The results reported from the operation of the law also suggest more rational and optimistic views of this problem than have been usually prevalent. Throughout, the author compares his findings with those of others and quotes figures extensively from the literature. Divergences of result are stressed as indications for real scientific study and for the abandonment of bias for fact. The style is self-assertive, and the writer often appears to be unnecessarily contentious. The general trend of the discussions, however, is healthy and pragmatic, and the tabulations will be found valuable for reference and comparison.

Rats and How to Destroy Them. Dealing with Rats in a House, Shop, Warehouse, Outbuilding, Yard, Stable, Cow-House, Fowl-house, Pig-sty, Garden, Greenhouse, or Vinery; by a River, Stream or Ornamental Water; on a Ship, Shooting Estate, or Farm; and in Sewers. By Mark Hovell, F.R.C.S., with introduction by S. L. Bensusan. Cloth. Price, $5. Pp. 465, with 51 illustrations. New York: William Wood & Co., 1924.

Mr. Hovell does not underestimate the acumen of rats; and he surely does not overestimate the intelligence of the men who catch them. His work is reminiscent of Izaac Walton, Dan Beard and the Pied Piper of Hamelin rolled into one. For forty years or more, the author has been taking notes, making experiments, inventing traps and covers for traps, devising signal systems, and analyzing poisons, mixing his own and testing their worth. Traps, runs and shelters for the traps have been made with his own hands, tried on his own property, and found worthy of public acceptance and use. "We must destroy these worst of all vermin," says the introduction, "for if we fail to do so, they will destroy us. Not only will they add very many million pounds a year to our national losses, but they will thrive so upon our negligence that Nature, the divinity that shapes our rough-hewn ends, will become alarmed at their numbers and send the plague among them. This plague is communicable to man in bubonic or pneumonic form, as most people know."

Modern Operative Surgery. Edited by H. W. Carson, F.R.C.S., Senior Surgeon, Prince of Wales's General Hospital. In two volumes. Cloth. Price, $20 per set. Pp 1568, with 741 illustrations. New York: William Wood & Co., 1925.

In the preface to this work, the editor says: "This is an attempt to present to the profession an authoritative survey of the whole range of modern surgical operations." And: "My aim has been to exclude operations which have lost their usefulness, and among new operations to include those only which have *proved* their value." These two statements virtually take the wind out of the sails of any one attempting to review the work; first, because it would mean to assail the wisdom and attainments of the editor as one not competent to decide what to exclude and what not; and, secondly, because the contributors have been selected with great care; they are men of acknowledged ability, and their word has been accepted as law, although no more binding than that of other equally well equipped men. Only controversial argument would result from any attempt to make a critical review—especially as the reviewer, in turn, presents only his own views. Among the contributors and their subjects are: Blomfield, anesthetics; Gauvain, surgical tuberculosis; Elmslie, general orthopedics; Handley, malignant disease and breast; Turner, liver and other structures; Walton, intestinal stasis; Verrall, joints; Hey-Groves fractures; Platt, nerves; Drummond, rectum; Rawling, skull and brain; Choyce, the tongue; Gillies, plastic surgery; Thomson-Walker, kidney and ureter, bladder, prostate and urethra. Only English surgeons have made contributions, and each of them has been exceedingly conservative in presenting his views. Some subjects apparently receive scant notice; some are omitted, but, remembering what the editor says in his preface, these sins of omission and commission can always be charged to the fact that whatever is not mentioned either has been discarded by the best surgeons or has not yet been accepted as really worth while. No attempt is made to present any subject in essay style, but merely in the form of present day actual knowledge. Speculation is not indulged in anywhere. Each topic is discussed systematically with reference to preoperative preparation and treatment, choice of anesthetic, asepsis and antisepsis, and general principles of technic and after-treatment. Results from many sources are presented, but, in keeping with the underlying idea of the work, no attempt is made to make any extensive references to literature. The writers apparently limit themselves to the presentation of what they regard as known and accepted facts, and quote only such references as bear on these facts. With that style one can have no quarrel, especially as this work is not heralded as a textbook. It is a record of the personal views and convictions of well known English surgeons, and as such will no doubt prove of great interest to all surgeons. The text is well written; it is clear and—with emphasis—concise. The illustrations are all original, a distinct novelty in books, although not without a precedent, an American surgeon who recently finished an extensive work on operative surgery having used only original drawings. The illustrations really illustrate, artistic merit often being sacrificed to clarity of depiction of an operation. On the whole, the work possesses much merit and can be read with great profit and pleasure.

Pathologische Physiologie des Chirurgen. (Experimentelle Chirurgie.) Ein Lehrbuch für Studierende und Aerzte. Von Prof. Dr. Franz Rost, Leitender Arzt der chirurgischen Abteilung des stadtischen Krankenhauses Mannheim. Third edition. Paper. Price, 27 marks. Pp. 626. Leipsic: F. C. W. Vogel, 1925.

Perhaps the greatest single advance in the surgery of the last decade is represented in the domination of surgical thought and procedure by the physiologist. Such fields of surgery as the thyroid, spleen, liver, gall tracts and stomach are noteworthy examples of this advance. This volume, dealing with pathologic physiology, includes in its scope every region of the body accessible to the surgeon. Its aim is to correlate the physiology of malfunction with symptomatology, and to establish a logical basis for corrective surgery; as the author puts it, "to provide a link between the student and the physician in the interpretation of diseases of the human body." The modern surgeon must be more than a mere mechanic. He must know and recognize living pathologic change. He must know, for instance, the significance of the exudate in peritonitis, or the effect of the various operative procedures advocated for ulcer on the motor mechanism of the stomach. He must know and recognize the various signs of malfunction as they contraindicate surgery. The development of the functional test in surgical diseases may be cited as example. The volume includes chapters on the digestive tract, kidneys, thyroid, chest, central and peripheral nervous systems, and the extremities. In this edition are valuable contributions on lymphatics, arthritis, arteriovenous aneurysm, and bone and joint tuberculosis. The work may be said to stand foremost among monographs on this phase of surgery.

The Animal as a Converter of Matter and Energy. A Study of the *Rôle of Live Stock in Food Production. By Henry Prentiss Armsby*, Director of the Institute of Animal Nutrition, Pennsylvania State College, and C. Robert Moulton, Professor of Agricultural Chemistry, University of Missouri. *Cloth. Price, $3. Pp. 236.* New York: The Chemical Catalog Company, Inc., 1925.

The new monograph of the American Chemical Society series coming from the late authority Dr. H. P. Armsby and from an authority of wider range, Dr. C. Robert Moulton, will no doubt be welcomed by those associated with various phases of the production of meat products. The main title is no doubt rather misleading, in that the book hardly attempts to present fundamental facts and problems but treats the subject more from the standpoint of technical information, as more accurately suggested by the subtitle. The book is divided into two parts. The first part, on the chemical processes of conversion, covers in elementary fashion the composition of feeding stuffs, the composition of the finished products resulting from stock raising and a brief discussion of digestion, absorption and metabolism. This part of the book is valuable from the standpoint of the tabular statements of composition there compiled, but does not give the most accurate account of such topics as maintenance of neutrality. The second part is on efficiency of conversion and gives in some detail the methods of investigation used and the results obtained. The material presented should prove of considerable value to scientific workers associated with stock raising and milk production. The book is well indexed and contains many valuable bibliographic footnote references.

Synopsis of Midwifery and Gynaecology. By Aleck W. Bourne, B A., M.B., B.Ch., Senior Obstetric Surgeon, Queen Charlotte's Hospital, London. Third edition. Cloth. Price, $4.50. Pp. 434, with 171 illustrations. *New York: William Wood & Co., 1925.*

This is an excellent synopsis of obstetrics and gynecology. The first part, on obstetrics, is written in outline form. It is fairly complete and authoritative, giving the English obstetrician's point of view. The value of this section has been greatly enhanced over previous editions by the use of many well made illustrations. The second section is an outline of gynecology, very thorough, even including the relatively recent pathologic entity called endometrioma. The pathology of the various conditions is well described. In general, the book is well adapted for reviewing the subject quickly.

Miscellany

COLONIZATION OF ARRESTED CASES OF PULMONARY TUBERCULOSIS ON FOREST RESERVE LANDS

Our nation, exclusive of Alaska and our overseas dependencies, embraces 3,000,000 square miles of land surface. Twenty per cent. of this would mean 600,000 square miles of forest area. Proper management and working of our forest lands would increase fourfold the present output of timber, a supply sufficient for the needs of our land for all time. The deep ravines, securely damned up, could better distribute and control the water output, giving us the use of it when most needed in the summer time. The power so generated would be almost incalculable. It is sufficient to state that at present not 1 per cent. of our flood water is utilized; the rest of it is lost, and all too often works ruin during its mad rush to the sea. Were all of our available water supply put to use we could multiply ten times over the power at present generated in the United States, and we would be using an endless chain of power, and not a perishable one as is the case today. The coal will some day all be gone; the water power we shall have forever. Furthermore, as an added advantage, at least 1 ton of food fish per acre could be produced every year from these artificial lakes, a sum total that would be an immense addition to our food supply. Turning again to the land surface, every thousand acres of forest land could be made to yield each year 200 deer as an addition to our present meat supply. If the entire forest area was so utilized, more than 70,000,000 deer could be provided annually. Elk or other game might be substituted, but in any case it would be an addition to our present meat total, for it would not be taking up much of the area now used for pasture purposes. The income that can be derived from the very waste heaps of our present lumbering methods would yearly run far into the millions. Today these heaps of slashings and scrap stuff are even more than waste—they are a positive source of danger to the standing timber. Left lying dry on the ground, the spark of the carelessly thrown match all too often ignites them and a blackened hillside tells the tale of loss from fire. From them could be obtained immense quantities of alcohol, oxalic acid, acetic acid and creosote. From the waste heaps of the pine lumber camps in the South, many millions of dollars' worth of turpentine could be produced annually. Our tannic acid output could be nearly doubled from the chestnut lumbering refuse, and our present pulp-wood supply could be multiplied several times over from the other lumber waste. At present the United States government and the various state governments own 227,117 square miles of forest reserve land. Let us begin at once really to work these holdings so as to get all out of them we properly can, and in almost no time they will be not only self-supporting but revenue producers as well. The present force, however, at work on them is but a very small fraction of the quota required to do the work completely. Here we could find places for every arrested case of tuberculosis in the United States. All over these forest holdings should be established little colonies and settlements where we could place our tuberculous patients strong enough for work, and here they might begin anew the battle of life. No longer dependent, they would be once more men among men, again adding their quota to the productive forces of the nation. More than this, they would not have to feel that in thus finding work they were taking work from others. Far from it; they would be adding to the actual working force of the country and could stand independent and foursquare with the world. A good many of our men would be able also to do patrol work, looking out for forest fires from watch towers and other points; others could be engaged in surveying and research work, and as they gained strength could help in the making and looking after roads and trails and fire lines and thinning and harvesting timber. Also, they could find employment in power plants and as game and fish wardens, guides for camping parties, work in insect control, collecting tree seedlings, and building and repairing telephone lines. Willow plantation work and the making of willow-ware articles could, much of it, be done by women as well as men. Then there is a big field in the making of wood novelties along with the manufacture of baskets and various bark articles. This plan for the combined conservation of man and timber may seem visionary and far away today, but it is a very feasible and very practicable one, and some day it surely will be done.—Rothrock, A. M.: *U. S. Veterans' Bureau M. Bull.* **1**:32 (Dec.) 1925.

CONFERENCES ON HEROIC REMEDIES

Most of the organized governments of the world were represented at the Second International Conference on the Unification of Formulas of Heroic Remedies held in Brussels, Belgium, September 21-29. The United States government and the Revision Committee of the U. S. Pharmacopeia were represented by A. G. DuMez, who reports, in part:

> The session was devoted to the adoption of rules governing the work of the conference and to the appointment of committees to consider and report on Topics 1, 2, 4, 5, 6 and 9 of the program, an outline of which follows:
>
> Topic 1. Revision of the decisions of the first conference.
> Topic 2. Unification of the formulas of other heroic remedies.
> Topic 3. Unification of arsenic and bismuth compounds.
> Topic 4. Unification of chemical methods of assay of certain medicaments.
> Topic 5. Unification of biologic methods of assay.
> Topic 6. Unification of maximum doses.
> Topic 7. Examination of the proposition to adopt a characteristic container for remedies intended for external use.
> Topic 8. Regulation of international commerce in narcotics.
> Topic 9. Examination of the project to create a permanent international secretariat of pharmacopeias.
>
> It was unanimously agreed that Topic 8 should be stricken from the program, as the subject was already being dealt with by a special committee of the League of Nations.
>
> Subsequent plenary sessions were held, September 22, 23, 25, 26 and 29. At these sessions, there were considered, in addition to Topics 3, 7 and 9 and the reports of the committees, several special propositions, namely: (1) A proposition to adopt a chemical method of standardization of the arsenicals, submitted by Dr. De Myttenaere of Belgium. (2) A proposition to adopt extracts of unit strength to be used in the preparation of other galenicals, submitted by the Swiss delegation. (3) A proposition to study the methods of dealkalizing glass containers intended for eye lotions and hypodermic solutions, submitted by the Swiss delegation. (4) A proposition to compile alphabetically in a small volume all the decisions on drugs and medicaments made by the conference, submitted by the Swiss delegation.

Medicolegal

Use and Weight of Examining Physician's Report

(Hart v. Industrial Accident Commission et al. (Calif.), 235 Pac. R. 748)

The District Court of Appeal of California, Third District, in affirming an award of the commission which denied compensation to an employee who met with an accident, says that an examining physician in the case wrote a letter describing the accident, what his examination revealed, and that his conclusion was that the patient had a right indirect advanced inguinal hernia, which was an old hernia as it was too large to have developed in five days, and tenderness was lacking. It was contended that a rehearing should be granted on account of the commission having received and acted on hearsay testimony; namely, the report of the examining physician. The existence of legislative sanction for the admission of such testimony was recognized, but the constitutionality thereof was questioned. The court does not agree with the contention, nor deem the law unconstitutional.

As to whether reports of examining physicians are reliable and whether credence may be given thereto and action based thereon are not matters for this court to determine. The legislature has amended the law so as to admit the receipt of such testimony by the commission, and the weight and credibility to be given thereto are for the commission, and not for the court.

A considerable portion of the petitioner's brief was given to a consideration of the causes of hernia, its origin, its symptoms and results, based on quotations from de Quervain on Clinical Diagnosis and Buckman's Operative Surgery. These writers differed somewhat from the conclusions reached by the examining physician, but this court had no means of determining whether these writers were more accurate in their statements, or better informed, or more likely to give correct information, than the examining physician. The argument of counsel reduced to a simple statement was the placing of hearsay testimony against hearsay testimony, the writing found in a book against the writing constituting the report of an examining physician. The court thinks the commission was justified in acting on the report of the examining physician, rather than on theories or suppositions or statements found in books, because the writer of the report undoubtedly knew at the time of making it that he was subject to the call of the commission and could be specifically and thoroughly interrogated as to any matters or statements contained in it. In any event, these were matters for the commission, and were within the exclusive jurisdiction of the commission.

Chiropractor Not a "Legally Qualified Physician"

(Isaacson v. Wisconsin Casualty Association (Wis.), 203 N. W. R. 918)

The Supreme Court of Wisconsin says that during a portion of the time for which the plaintiff sought to recover a sick benefit under an accident insurance policy he was attended by a chiropractor. The policy required, as a condition of the payment of the sick benefit, that the insured should be attended by "a legally qualified physician," and the defendant argued that, since the Wisconsin statute provides that "reputable practitioners of chiropractic may practice their profession in this state, if they do not hold themselves out as registered or licensed, and conspicuously display in the places where they practice a sign containing in large and legible type: 'Not registered or licensed in Wisconsin,'" they are not to be classed as regularly qualified physicians.

It is a well known fact that chiropractors specialize in certain classes of diseases; that ordinarily they do not administer medicine or treat certain classes of diseases very common to humanity. It is not here intended to determine whether or not specialists who are regularly licensed come or do not come within the terms "legally qualified physician," as used in the policy. But it seems quite clear that, in using the term "legally qualified physician," the insured as well as the insurer meant a physician who was qualified and licensed to practice, and that the term did not include a specialist in body manipulations only, such as a chiropractor. Many forms of sickness attack persons that chiropractors do not pretend to treat at all. It was undoubtedly the idea of the insurer, in choosing the term "legally qualified physician," to include only persons who could aid and treat all classes of ailments to which the insured might be subject, and that where, as here, there was a case of rheumatism and pleurisy, the services of a regularly qualified physician, one who might and would prescribe and administer medicine as well as perhaps employ body manipulations, was intended

As stated in briefs by both counsel, the term "physician" is one of very wide significance and colloquially speaking includes the term "surgeon" and many specialists within the field of medicine It is the broadest term our language contains applicable to one who practices medicine, including both medicine and surgery in its original meaning This court therefore reaches the conclusion that the trial court erred in holding that a chiropractor was a "legally qualified physician" within the meaning of the policy, and the judgment rendered will be modified by deducting the amount allowed the plaintiff for disability during the time that he was not treated by a "legally qualified physician"

Employer Liable for Roentgen-Ray Burn in Examination

(Lincoln Park Coal & Brick Co v Industrial Commission et al (Ill), 148 N E. R 79)

The Supreme Court of Illinois says that an employee was injured in the course of his employment in February, 1921 He was voluntarily paid $533 07 compensation by his employer. He returned to work, but insisted that he had only partly recovered, and that he was entitled to further compensation, which was not agreed to by his employer, and he filed an application for the adjustment of his claim The employer demanded that the employee be examined by a physician selected by it On March 10, 1922, he submitted to an examination in the course of which roentgenograms were made by the physician On March 12 an agreement was made for a settlement on payment of $200, which was approved by the industrial commission About three days later the employee discovered that he had been burned on the abdomen by the roentgen-ray machine The evidence disclosed that the burn caused a rather serious condition On April 24 he filed a petition for review under the workmen's compensation act of Illinois The industrial commission made an award, ordering the employer to pay him $12 a week for 230 57 weeks, commencing April 24, 1922, and thereafter a pension for life of $23 33 a month, and $382 75 on account of medical and hospital services The circuit court set aside the award, but the supreme court reverses the judgment of the circuit court and affirms the award of the industrial commission, after deducting $128 40 from the award for medical and hospital services, which it was admitted should have been $254 35, instead of $382 75

The employee contended that, as he was required by the employer to undergo the examination by the physician who was its agent in making the examination, the injury inflicted by the examination was the proximate result of the original injury The employer, on the other hand, contended that the proceeding authorized by paragraph (h) of Section 19 of the compensation act, under which the employee filed his petition for further compensation, was for compensation for a recurrence or increase of disability from the original injury, and did not authorize an award of compensation for injury from any intervening cause; that the burn, although resulting from the examination which the law authorized the employer to require the employee to submit to, was in no sense a recurrence or increase of the disability for which compensation was authorized and in no way was connected with or related to the injury for which compensation was claimed.

The question was a novel one, and counsel for the employer stated that diligent search had failed to disclose any case which had decided the exact question They contended, however, that the weight of authority is that the employer is not liable, under the workmen's compensation act, for injury resulting from the malpractice of a physician, and that, while that was a different question from the one here involved, there was some analogy between the two questions. But this court believes that it was never contemplated that the statute should authorize the employer to compel an examination by a physician selected by the employer to determine whether the employee is suffering any incapacity from an injury for which the employer is admittedly liable, and if the physician making the examination, through negligence or lack of skill, inflicts an injury which causes disability, the employer should not be liable under the statute. As the injury for which the employee was seeking compensation in this case would not have occurred except for the examination required to be made by the employer, this court is of the opinion that it was so related to, and connected with, the injury as to authorize an award of compensation In certain cases this and other courts have held that where there was an injury which lowered and weakened the vitality of the employee, and an independent disease was contracted which caused death, it would be attributed to the injury and not to the disease. If those decisions are sound—and this court certainly believes they are—the construction was warranted that the employer was liable to pay compensation in this case.

Damages Allowed for Colds

(St Louis San Francisco Ry Co v McHaffey et al (Ark), 271 S W R 452)

The Supreme Court of Arkansas says that a train on which the plaintiffs were passengers was, by a collision in front of it, delayed from 7 p m. until 3 or 4 o'clock the following morning, and, the engine being detached to assist in removing the debris caused by the collision, the coach in which the plaintiffs were became very cold, the temperature falling to 16 or 18 degrees below zero On account of the exposure during the night, the plaintiffs all contracted severe colds Mrs McHaffey was indisposed for two or three weeks; an elder daughter was confined to her bed, and barely escaped pneumonia, while two children soon recovered. None of the family suffered any permanent injury on account of the exposure, and, aside from the elder daughter, none of them suffered intensely At the conclusion of the testimony in all the cases, the defendant railway company admitted liability and asked that the jury be instructed as to the measure of damages only The elder daughter recovered a judgment for $1,000 damages, Mrs. McHaffey, one for $800; and each of the two children, one for $100. The company appealed, contending that the judgments were excessive, and the supreme court thinks that, under all the circumstances, they were; wherefore it holds that a remittitur must be entered reducing each judgment one half; otherwise the judgments would be reversed and the cause remanded for a new trial.

Society Proceedings

COMING MEETINGS

American Pharmacological Society, Cleveland, Dec. 28-31. Dr. E. D Brown, University of Minnesota, Minneapolis, Minn , Secretary.

American Physiological Society, Cleveland, Dec 29 31. Dr. W. J. Meek, Science Hall, Madison, Wis

American Society for Experimental Pathology, Cleveland, Dec 28 30 Dr. E B Krumbhaar, Philadelphia General Hospital, Philadelphia, Sec'y

American Society of Biological Chemistry, Cleveland, Dec 28 30. Dr D W. Wilson, University of Pennsylvania School of Medicine, Philadelphia, Secretary

Federation of American Societies for Experimental Biology, Cleveland, Dec 29 31 Dr Walter J Meek, Science Hall, Madison, Wis , Sec'y

Isthmian Canal Zone, Medical Association of, Ancon, Jan 19. Dr. David L Robeson, Ancon Hospital, Ancon, Secretary.

Philippine Islands Medical Association, Manila, Dec 16 19 Dr Isabelo Concepcion, College of Medicine and Surgery, Manila, Secretary

Porto Rico, Medical Association of, Coamı, Dec 14 15 Dr. R M. Suarez, Box 314, Santurce, Secretary

Sioux Valley Medical Association, Sioux City, Iowa, Jan. 19 20. Dr. R F. Bellaire, Trimble Block, Sioux City, Secretary

Society of American Bacteriologists, Madison, Wis , Dec 29 31. Dr. James M Sherman, Cornell University, Ithaca, N Y., Secretary.

Southern Surgical Association, Louisville, Ky , Dec 15-17. Dr. Hubert A. Royster, 423 Fayetteville Street, Raleigh, N. C., Secretary.

Western Surgical Association, Wichita, Kan , Dec 18-19. Dr. Harry P. Ritchie, Lowry Building, St. Paul, Minn , Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL for a period of three days. No foreign journals are available prior to 1920, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

- New Electrode for Clinical and Experimental Electrocardiography. G. R. Hermann, New Orleans, and F. N. Wilson, Ann Arbor, Mich.—p. 111.

Death Due to Latent Syphilitic Myocarditis.—The eight cases reported by Warthin show that sudden death may occur in latent syphilis as the result of an acute exacerbation of previously mild, latent processes in the heart and aorta. The pathologic character of the active lesions differs from that of the chronic lesions in the more marked edema and the greater polymorphonuclear cell content of the infiltrations. In this respect these acute lesions resemble the perivascular and vascular infiltrations of active syphilis of the umbilical cord in which the cells are predominantly polymorphonuclears and the number of spirochetes enormous. They correspond also to the "critical reaction" described by Brown and Pearce in experimental animal syphilis in which there is a diffuse edema and polymorphonuclear infiltration in the rapidly developing syphilitic lesions followed by a rapid resolution. Similar lesions occur in the earliest stages of the syphilitic process, and in lesions of malignant type before ulceration occurs.

Prognosis in Subacute Bacterial Endocarditis.—Libman reports on a study of over 800 cases of subacute bacterial endocarditis, extending over a period of twenty-five years. He has found that there is a small number of spontaneous, complete recoveries. There is a surprisingly large number of cases that come under observation with the sequelae of a former attack of the disease, either just before or directly after the infectious stage has terminated, or, more commonly, without any clinical recognition of the attack. Mild cases of short or long duration occur. The disease may exist in recurrent form. In the course of healing, the lesions of subacute bacterial endocarditis play a rôle in the development of chronic valvular disease.

Sympathectomy in Angina Pectoris.—A detailed report is made by Levine and Newton concerning seven patients who were selected for sympathectomy. They are all alive from three months to two years following operation. Three were rendered absolutely free from anginal attacks immediately and have remained so. Three continued to have typical anginal attacks after the operation but were nevertheless considerably improved, in that it required a greater effort to bring the attacks on. One was made neither better nor worse. Of these latter four, three have since become practically free from attacks as a result of medical care. An eighth patient died on the day of the operation. It had been decided after careful study that this case was a distinctly unfavorable one to be treated surgically, but because the patient was growing worse and life was becoming unbearable despite a ten weeks' course of medical care, including antisyphilitic treatment, the operation was performed although the operators were fully aware of its dangers. In general it is felt that the operative measures for angina pectoris if carried out on properly selected patients are a distinct addition to therapy.

Economic Phases of Heart Disease.—Carr states that about one half of the patients with chronic heart disease with decompensation are of an age at which the earning capacity should be at its maximum and family responsibilities are likely to be most pressing. These persons are affected with a disease which causes partial disability for years and total disability extending, on the average, over a year and a half. In a single dispensary, one third of the families represented were dependent on charity for their sustenance. Figures have been presented from two institutions which show that the economic loss, private and public, covering only a fraction of the patients with heart disease in one of our large cities, must be estimated in hundreds of thousands of dollars annually.

Heart in Myxedema.—In 162 cases of high grade myxedema studied by Willius and Haines, no case of heart failure and no case of organic cardiovascular disease was found that could be justly attributed to the myxedema. There were numerous electrocardiographic abnormalities which disappeared under thyroid medication. The data presented do not justify the establishment of a cardiac syndrome characteristic of myxedema.

Postural Hypotension.—The one feature of outstanding interest and importance common to the three patients whose histories are given by Bradbury and Eggleston is the extraordinary dependence of the systolic and diastolic blood pressures on the influence of gravity, as exerted through alterations in the positions of the body from the horizontal. The rise of blood pressures in the head down position, and their fall in the foot down or the erect position, occurs almost immediately. The reactions are those which would be expected if the whole peripheral vascular bed were always wide open, inelastic and capable of accommodating the major proportion of the entire blood volume of the body. This is the only definite conclusion to which investigations have led the authors. The cause or causes of this remarkable absence of normal vasomotor control seems to be purely speculative. Efforts to cure these patients, or to control their disorders, have been unavailing. These efforts have included the administration of thyroxin, epinephrin, dried suprarenal substance, mixed glands, strychnin and digitalis, and the enforced consumption of sugar and of water. Paralysis of the sympathetic vasoconstrictor endings seems to be the only adequate explanation of the blood pressure reactions observed in these three cases. It accounts for the absence of vasoconstriction following the injection of epinephrin. And it explains the total absence of the normal vasomotor control by which blood pressure is maintained at a nearly constant level in the face of changes in the position of the body in normal persons.

Circulation of Heart Valves.—Further confirmation of the embolic conception of endocarditis is presented by Kerr and Mettier. They point out that further evidence is needed to prove the identity of rheumatic and subacute bacterial endocarditis, but recent investigations are more than suggestive.

Micro-Organism of Granuloma Inguinale.—In three cases of granuloma inguinale studied by Cornwall and Peck, organisms that they believed to be identical were isolated. Lesions resembling clinically and pathologically those observed in humans were reproduced in rabbits by intracutaneous inoculation. An organism apparently identical with the one cultured from human lesions was obtained in cultures from rabbit lesions. Lesions were produced by reinoculation from rabbit to rabbit, and an organism was recovered from the second rabbit that seemed to be identical with that isolated from man. The organism isolated undergoes a characteristic morphologic change in young cultures on Sabouraud's medium. This morphologic change disappears in old cultures, and is not reproduced in subcultures.

Sporotrichosis in Montreal. — A case of sporotrichosis occurring in a patient in Montreal is reported by Burgess. Apparently this case represents a somewhat unusual type of the disease, and probably is best described as a single sporotrichotic gumma. The causative fungus is *Sporotrichum beurmanni*. Of interest was the slow response to potassium iodid, a drug that usually results in a relatively quick involution of these lesions. A six months' course of treatment with large doses of potassium iodid was necessary before complete recovery resulted.

Protein Diet in Pellagra. — Mook and Weiss report two cases of pellagra in which a pure protein diet was given. In one case complete recovery occurred on this diet but in the other it was necessary to add sufficient fat and vitamin together with digestive ferments to satisfy the caloric requirements. A point of interest in this case was the fact that the disease was self-induced. The patient, aged 16, decided to reduce her weight. The regular diet in her family was not well balanced, and the patient, by omitting one meal daily and using a preponderance of carbohydrate and fat, succeeded in reducing her weight but produced a self-induced pellagra.

Curative Effect of Bismuth Compounds in Syphilis.—On the basis of prolonged observations and the method of popliteal node transfer, Raiziss and Severac found that bismuth compounds are powerful enough to cause complete eradication of infection in experimental rabbit syphilis. However, because the low toxicity of arsphenamin derivatives permits the intravenous administration of massive doses, they remain the basic remedies in the treatment of syphilis, bismuth compounds taking the next place.

Normal Blood Cholesterol Curve.—A list is submitted by Weidman and Sunderman indicating the normal range of "whole blood" cholesterol in various animal species, and showing in order which species have the highest values. From this it appears that there is no relation between the dietary habits of animals and blood cholesterol content.

Tubercle Bacillus as Cause of Lupus Erythematosus. — Tuberculosis, both macroscopic and microscopic, was produced by Cannon and Ornstein in guinea-pigs inoculated with biopsy material from five of twenty-three cases of lupus erythematosus. This fact, while not conclusive proof, would point to the tubercle bacillus as the etiologic factor in this disease. The hypersensitiveness to tuberculin, general, local and focal, is suggestive of the tuberculous nature of this disease.

Flumerin in Syphilis of Eye.—Hogan and Robertson discovered accidentally that flumerin is of value therapeutically, the initial dosage in all cases being 3 mg. per kilogram of body weight. The dose was increased according to the amount of salivation and the urinary findings. In most of the cases in which more than 0.2 gm. of the drug was given, there was a gingivitis. This was not severe, however, and usually disappeared in from forty-eight to seventy-two hours. In a few instances, following large doses, the patient complained of tenesmus, and in two or three instances, there was diarrhea, but only in one instance was this of a bloody character. The treatment should be started with 0.15 gm. and raised in doses of 0.05 gm. until a point of tolerance has been reached. One man, weighing 112 pounds (50.8 kg.), was given as high as 0.8 gm. without showing any urinary changes, diarrhea or tenesmus, and only a slight gingivitis. Another advantage of increasing the dose of this drug over the other preparations of mercury is that the symptoms of hydrargyrism become apparent within a few hours, and one does not have to anticipate cumulative action causing salivation, hematuria and gastro-intestinal distress.

Value of Colloidal Benzoin Reaction.—A not inconsiderable experience with this test has convinced Osborne that it is superior to the colloidal gold test in its ease of performance, uniformity of result, reliability and amount of information furnished. It should have a wide field of usefulness in differentiating general paresis and incipient general paresis from the other forms of neurosyphilis.

Closed Foramina of Luschka in Brains of Insane. — An investigation was made by Bateman to determine in adult human material the closed or open condition of the lateral apertures of the fourth ventricle (foramina of Luschka). It was soon found that pouch-like closures of these foramina existed in many of the brains of the insane as well as of some normal persons. The material consisted of 901 brains; 666 were from insane persons, 150 from epileptic persons and eighty-five from presumably normal persons. Eighty-seven closures of the foramina of Luschka were found; sixty-seven of these were unilateral. In brains of the insane the percentage of closures was 11.6; in brains of epileptic persons, 5.3; in normal brains, 2.5. The evidence presented points in one direction; namely, that the marked unilateral deterioration of nervous substance observed in these cases may be interpreted, at least in part, as the result of inadequate circulation with stagnation of the fluid, and an accumulation of waste products due to such a type of obstruction as a closed foramen of Luschka on the same side.

Is Encephalitis Infectious Disease?—Salzman reports ten cases of encephalitis showing distinct infection in the gallbladder. These patients were treated for the most part surgically, with remarkable improvement in the encephalitis and clinical recovery in a few days. This experience in Salzman's opinion justifies the assumption that the encephalitis present in these cases was due to selective action of a toxin caused by infection within the gallbladder.

Reactive Gliosis in Brain Tumor.—The opinion of older writers that there is actual neuroglia overgrowth throughout the hemisphere which is the seat of a glioma, is borne out by a carefully controlled photographic study made by Freeman on unimpeachable material.

Psychosis Associated with Trauma of Head.—Taft and Strecker report a case of trauma sustained in infancy which determined a later developing dural tumor. The patient died at the age of 68, the last thirty-six years of her life being spent in a hospital for mental disease. Her psychosis suffered at the hands of changing psychiatric nomenclature. For many years, it was designated "chronic mania"; later, the opinion veered to dementia praecox. The patient sustained a fractured skull in infancy, and either it alone or in conjunction with the so-called "brain fever" (meningitis?) resulted in a partial left hemiplegia. At the end of the third decade of her life, her personality changed and she began to behave in a manner which, in the light of the injury of the head, suggested the likelihood of the development of a so-called traumatic constitution. At about this time she was placed in a hospital for mental diseases, and for at least twenty-three years had a psychosis marked by manic-like symptoms, but with enough disintegration to suggest dementia praecox. During all these years, there was only a single reliable objective phenomenon, namely, the "convulsion" six years before, which might have brought the head injury into consideration as an etiologic factor. The brain was removed immediately after the patient's death. On the inner surface of the dura, about at a point corresponding with the lower extremity of the central fissure, was a small, sharply circumscribed tumor, 2 by 1.25 by 1 cm. in diameter. The tissue showed the characteristics of meningeal endothelioma.

Fractional Ligation of Carotid in Pulsating Exophthalmos.—Kerr reports three cases of pulsating exophthalmos in which treatment was by common carotid ligation done by the original method of fractional ligation. In all cases the results were as good as could be expected. The operation was done in two stages. First, under local anesthesia, a strip of fascia lata from the thigh was passed around the common carotid below the bifurcation. The artery was gradually constricted until the pulsation of the eyeball ceased, but not to a sufficient extent to produce signs of cerebral anemia. The patient, being conscious, was able to cooperate in guiding the operators to a nice exactness of the extent of occlusion that could be made on the artery, short of producing serious symptoms. When this had been accomplished, the fascial band was sutured in situ with chromic catgut. The lumen of the artery had been reduced by about 50 per cent. by the maneuver. The wound was then closed. The immediate results were gratifying, in that the patient was not aware of the previous annoying bruit, though it could still be heard with the stethoscope. Three weeks later the vessel was again exposed through the former incision, and the common carotid artery ligated with a double ligature above the fascial band.

Nature of Menstruation.—The conclusion is reached by Ludlum and McDonald that menstruation is a time of vagotonia or vagus stimulation and that this can be shown in the smooth muscle reaction of the intestine. The wave of vagus preponderance begins from eight to two days before menstruation, reaches its height during the menstruation and returns to the intermenstrual condition from three to six days after menstruation. There is some evidence that among other factors this vagus preponderance is, in part at least, due to the accumulation of calcium in the blood and tissues and that calcium is cast off at the time of menstruation. It is possible that some of the preliminary pains of menstruation are due to intestinal cramps from vagus stimulaton. Drugs and salts which reduce the vagus stimulation relieve the menstrual pain.

Bronchoscopic Treatment of Lung Abscess.—A review of thirty-two cases of lung abscess in which bronchoscopy was systematically done by Myerson is given. Six patients were cured; nineteen were improved and four received no benefit from the treatment. Two patients died.

Intracranial Complications of Posterior Sinus Infections.—A case of suppurative posterior ethmoiditis and sphenoiditis with complete destructon of the optic nerve is described by Fink. The true intracranial pathologic condition was overlooked because attention was focused on the obvious manifestations of syphilis. The unilateral exophthalmos and primary optic atrophy should have suggested cavernous sinus thrombosis, but the patient entered the hospital in the terminal stages when the acute manifestations of nasal infection were forgotten. There was no evidence either grossly or microscopically of syphilitic involvement of the bony walls of the sinuses. The only influence of syphilis on the pathologic condition in this case was the interference with proper drainage produced by syphilitic scars in the nasopharynx.

Patellar Anomalies Mistaken for Fracture.—In a series of thirty-six cases of fractured patella reviewed by Adams and Leonard, in over 3 per cent. congenital anomalies were erroneously diagnosed as fractures.

Persistent Sac in Inguinal Hernia.—In a series of cases in which the inguinal canal was opened on account of a relaxed ring and in which no clinical evidence of hernia was seen, in every instance a small persistent sac was found. Analysis of a group of cases by Hughson shows that 16 per cent. of the patients presenting hernia on one side eventually develop hernia on the opposite side. It is felt that correlation of these facts lends further strong support to the preformed sac theory in regard to the etiology of all inguinal hernia. A study of 100 consecutive cases of both single and double herniotomies has shown that the double operation increases the incidence of postoperative pulmonary infections, but it does not increase the incidence of wound infection.

Retroperitoneal Cyst.—Cave reports a case of cystic tumor of the retroperitoneal space, not attached to any solid or hollow viscus, but supposedly originating in vestigial remains of fetal structures.

Peritonitis Ossificans. — Myers reports an ossification, apparently analogous to myositis ossificans, deserving the nomenclature of "peritonitis ossificans." Search of the literature has failed to reveal a similar case. The mass, measuring 4 by 9 by 12 mm., was found about the tip of an atrophic appendix. It was surrounded by omentum, which closely adhered to the mass in all of its nonappendiceal attachments.

The portion attached to the appendix was so firmly fixed that the peritoneal coat was stripped off in delivering the mass.

Leukocyte Count as Diagnostic Aid in Ectopic Gestation.—Farrar has reviewed 150 cases of ectopic gestation with reference to the leukocyte count. He found that it fluctuates according to the amount of fresh blood being thrown into the peritoneal cavity and the rate of absorption. The leukocyte count tends to drop quickly to normal as the blood in the peritoneal cavity is absorbed or walled in; in 48 per cent. of 150 cases of ectopic gestation, there was a normal leukocyte count before operation was performed. The leukocyte count was normal in twenty-nine cases of unruptured tubal pregnancy in which there was no free blood and in forty-three cases of ruptured pregnancy in which the blood was walled in. The leukocyte count was an index in 150 cases to the amount of free blood in the peritoneal cavity, and the polymorphonuclear leukocyte count was increased markedly only in cases showing fresh blood in the pelvis and increased in direct proportion to the amount of recent blood found at the time of operation. The fluctuating leukocyte count, together with the moderate elevation of temperature, differentiates ectopic gestation from a purulent salpingitis with its more uniformly high leukocyte count and fluctuating temperature. In cases of rupture of tubal pregnancy the steadily rising leukocyte count indicates active bleeding before the fall in the number of red cells or hemoglobin gives warning of the condition. The leukocyte count, to be of diagnostic value, must be taken at least daily and in critical cases even hourly and used in conjunction with the history and clinical findings in the case.

Relation of Duodenal Ulcer to Pulmonary Tuberculosis.—In an effort to procure additional information bearing on the relation of duodenal ulcer to pulmonary tuberculosis, Lisa has reviewed two series of necropsies performed by him. One of the series consists of 257 necropsies in cases of pulmonary tuberculosis, including cases in which the tuberculosis was primary in other systems but also showing pulmonary involvement; and for comparison, another series of 209 necropsies which showed no tuberculosis. In the first group there were nine duodenal ulcers; in the second group, four. The ulcer is usually nontuberculous in character. Pulmonary tuberculosis associated with duodenal ulcer is usually of chronic form. The age of most frequent occurrence of ulcer is from 25 to 35 years.

Total Gastrectomy for Linnitis Plastica.—Reid reports a case of linnitis plastica treated by a complete excision of the stomach. Restoration of the continuity of the alimentary tract was effected by an esophagojejunal and a jejunojejunal anastomosis. A study of the stomach revealed a diffuse sclerosing type of scirrhus carcinoma which involved all of the stomach except a small portion of the fundus. This operation was done in November, 1924. The patient, aged 51, has continued to take a soft diet and has gained weight. She has not vomited, and has recovered her health and strength to such an extent that she is doing her own housework. The only discomfort she experiences now is a sensation of fulness after eating small amounts of food. She is, however, gradually taking more food at a time. The only medication consisted of dilute hydrochloric acid, 10 minims, and pepsin solution, 1 c.c., three times a day. Since leaving the hospital the patient has continued to take the hydrochloric acid but has discontinued the use of the pepsin solution.

Renal Roentgenography During Operation.—Roentgenography of the kidney exposed at the operating table is shown by Sosman to be practical as well as practicable, and of great importance in operations for renal calculi. Its advantages over fluoroscopy under the same conditions are discussed. Twenty-five patients have been examined in this manner.

Determining Patency of Fallopian Tubes.—Seides uses a sphygmomanometer, a uterine cannula, a T tube, and some rubber tubing. The blood pressure cuff is detached from the syphgmomanometer and the T tube and cannula assembly connected with it. The bulb is worked in the same manner as when one takes the blood pressure. After the cannula is introduced into the cervix and properly adjusted, the bulb is compressed very gently so that the pressure rises only from 5 to 10 points with each compression. After each compression of the bulb the operator pauses a moment to note the rise of the mercury. When the pressure reaches a height sufficient to open the tube (in patent cases) and cause the escape of air into the peritoneal cavity, the mercury begins to drop, and continues to drop, until the pressure becomes equal to the resistance offered by the tube. At that point the mercury remains stationary. The bulb is now compressed again, driving the mercury up from 10 to 20 points. When the bulb is released the mercury falls rapidly to its former height or a little lower. Another compression of the bulb causes a repetition of the previous occurrence. This is evidence that the patency of a fallopian tube has been established. So small is the amount of air introduced by this method that the shoulder pain does not appear until after the patient has been up and about for several minutes. This pain though definite and unmistakable is so mild that, as a rule, it does not interfere with the patient's customary activities and disappears entirely within twenty-four hours.

Kahn Test for Syphilis.—In Houghton's opinion, the Kahn test possesses superior qualities over the Wassermann reaction and the various precipitation procedures now in use. It offers a standard and stable antigen which can readily be prepared in a central laboratory for supplying other laboratories. It offers a diagnostic procedure with serum, the specificity of which has not been questioned by a large number of workers. The procedure appears to be superior to any test available at this time, being influenced neither by contamination nor by anticomplementary properties. The Kahn test further offers a quantitative procedure which is of especial value as a check on treatment. None of the procedures of the Kahn test require incubation, all reactions being completed on mixing the ingredients and shaking for a few minutes. This renders it possible to obtain the results at any time instead of the usual once or twice a week serologic examinations.

Acute Hemorrhagic Encephalitis.—A fatal case of acute hemorrhagic encephalitis, with both inferior and superior involvement, but with symptoms which point to the predominance of the inferior type, toxic in origin, probably infectious and brought on and aggravated by trauma, is reported by Middlestadt. The symptoms presented in this case were probably due to the hemorrhages in the base of the brain and in the third and fourth ventricles.

Heredity in Relation to Mental Diseases.—From a practical consideration of the subject of insanity, Mott says it is very necessary to recognize that the germ cells of every person who is certified as insane and sent to a mental hospital are not necessarily possible potential transmitters of a mental disease. General paralysis of the insane and many other microbic infections leading to disordered mental functions are acquired diseases and are not hereditary. Nor is it right to assume that simple senile decay affecting the brain is transmissible, yet a large percentage of inmates of asylums are sent there on account of senility. These legal administrative conceptions of mental disease must therefore vitiate all statistics in respect to heredity as a cause of mental disease, because based on data in which admission to a mental hospital are in many instances the sole evidence. This does not apply to the same extent to carefully recorded pedigrees; but even these are not free from error, for often all the information that can be obtained is that one or more members of the stock has been in an asylum. Mott says further that the term "hereditary syphilis" is a misnomer. Much may happen while the embryo is still in utero. The normal biologic processes of nutrition of the developing embryo may fail; abnormal mechanical conditions may arise in the uterus, interfering with the proper development of the embryo; or mechanical conditions in the process of development of the embryo may arise, interfering with the development of the structure. Of all the structures in the body of the embryo likely to be affected by a departure from normal dynamic biologic conditions of growth, the great brain or cerebrum is the most likely. Many mechanical failures and accidents may occur, interfering with the vascular supply of nutrition of the rapidly proliferating cells, whereby the process may be arrested altogether, as in anencephaly, or partially arrested, as in the brain of the idiot or low grade imbecile. There is evidence of a possible vascular cause through a lack of correspondence in a normal rate of growth of the dura mater and soft membranes and the growth of the brain. Because of this, the veins enter the longitudinal sinus in a direction opposite to the current of the blood stream in the frontal lobes—an anatomic condition that favors venous stasis. Again, prolonged labor and difficulties in delivery requiring the use of instruments may be responsible for injury of the brain.

Biochemical Characters of Bacteria.—It appears from Castellani's experiments that, with regard to certain bacteria, when two species live in association or are artificially mixed, their mixture may present certain biochemical characters that neither species possesses when living separately. For example, *B. typhosus* alone produces acidity, never gas, in maltose, mannitol and sorbite; *B. morgani* alone produces neither acidity nor gas in these substances; the mixture *B. typhosus* plus *B. morgani* produces, however, both gas and acidity, although one would expect that by adding to a germ, which produces a simple acidity and never gas, one that produces neither acidity nor gas, there would still be only production of simple acidity. The phenomenon of fermentation with production of gas of certain substances, such as maltose, mannitol, and sorbite, by adding to a germ, which produces in them simple acidity and never gas, a germ that is apparently inert on those substances—that is, produces alone neither acidity nor gas in them—seems to depend to some extent on the fermental powers of the second germ on certain other carbohydrates. For instance, not all bacilli inert on mannitol will cause production of gas in that substance when added to *B. typhosus*, which produces in it only acidity; a condition for the phenomenon to take place seems to be that the added germ, although inert on mannitol, must be capable of producing acidity and gas in glucose. It must be noted, however, that not every organism producing gas in glucose and neither acidity nor gas in mannitol will cause production of acid and gas in the latter substance when added to a producer in it of simple acidity, such as *B. typhosus*.

Intestinal Hemorrhage Controlled by Coagulen. L. C. D. Irvine.—p. 918.

Nature of Urinary Protein.—Experimental evidence is submitted by Hynd which shows that the protein excreted in the urine in various conditions is not always identical. In the twelve cases investigated of "albuminuria of pregnancy" without convulsions, the specific rotation of the urinary albumin averaged — 55.81 degrees and thus agreed with that found for human serum albumin under similar treatment; namely — 54.47 degrees. A similar close agreement in specific rotation, namely, —54.25 degrees, was found in five cases of proteinuria not associated with pregnancy. On the other hand, the fourteen cases of eclampsia investigated were sharply divided into two groups, one group of six having an average $[\alpha]_D$ of — 56.37 degrees, and the other group of eight having an average $[\alpha]_D$ of — 38.5 degrees. The optical activity of the albumin in the former group agrees well with that of serum albumin (— 54.47 degrees), while that in the latter approximates closely that of cow's lactalbumin (— 41.17 degrees). Accordingly, it is suggested (*a*) that in certain types of eclampsia the urinary albumin may be mainly lactalbumin; (*b*) that eclampsia may be an anaphylactic reaction due to the circulation in the blood of this foreign protein; and (*c*) that the mammary gland may be an important factor in the causation of eclampsia.

Cerebrospinal Fluid After Malarial Treatment of Insane.—During the observation of eighty cases in which general paralysis was treated with therapeutic malaria, it has been found expedient by Nicole and Steel to reexamine the cerebrospinal fluid in twenty-five cases at varying dates after the termination of the pyrexia. More than half the cases now show a negative reaction to the globulin test, whereas all showed a positive result before treatment. As regards the colloidal gold reaction, even allowing for the human element in taking the readings, the changes more or less correspond in their occurrence with the conversion of a positive globulin reaction into a negative one; furthermore, the change has not only been the "displacement to the left and upward" mentioned by Pappenheim, but is also of the nature of a conversion of a true paretic reading to that more usually associated with a diagnosis of cerebrospinal syphilis. Of those patients admitted in an advanced condition of general paralysis (showing progressive dementia and faulty habits coupled with physical debility), out of a total of twelve, eight have shown no appreciable alteration in the reactions of the cerebrospinal fluid after treatment with malaria. On the other hand, definite changes in these respects have been shown in ten of the thirteen early cases.

Comparison of Cardiac Mortality in Johannesburg, Cape Town and Durban. E. Cluver.—p. 414.
Case of Myelogenous Leukemia. F. H. Dommisse.—p. 415.

Results from Suprapubic Prostatectomy.—Of the 143 cases in Mursell's series, sixteen patients died in hospitals or nursing homes, a mortality of 11.2 per cent. Fifty consecutive hospital cases, as distinct from private cases, showed a mortality of 14 per cent. The higher mortality is attributable to the fact that many of the hospital cases are of long standing, and the patients only present themselves for treatment when complete retention compels them to come.

Desensitization to Bee Stings.—Braun snipped off the posterior one-eighth inch of the body of the bee. This part of the body contains the poison bag into which leads the acid gland. The poison bag leads directly into the gorget or sting. The poison was extracted by grinding up in saline solution. To test for sensitivity in the patient, Braun scarified an area one-eighth inch square without drawing blood, and applied 1 drop of the solution. Within five minutes the spot became very red, and soon after a wheal formed, which spread rapidly. Within a further three minutes, the patient began to complain of a general reaction. The face and neck started to swell and the conjunctivae became injected. At the same time the patient began a peculiar sort of suffocating cough, which never ceased for more than thirty seconds. A violent tremor set in, which soon became generalized. The pulse mounted to 120, and altogether the patient's condition became rather alarming. The wheal at the site of vaccination became larger and larger, and soon the whole body was covered with a red urticaria which showed up dull white on stretching the skin. As the condition remained the same after about twenty minutes, and as the patient was beginning to show mental distress, Braun injected 10 minims of epinephrin. Gradually the signs and symptoms subsided, with the exception of the trembling, which persisted for some time. During this attack, the patient experienced bearing-down pains and mental anxiety. Desensitization was carried on by injecting gradually increasing doses until the patient was receiving 15 c.c. undiluted venom.

Familial Incidence of Progressive Muscular Atrophy.—Four of five children were affected in Mirvish's series of cases. The father and mother apparently were not affected. In all four cases the mode of onset was similar. Up to the age of 17, the patients were perfectly healthy and normal; they attended school, and used to run and play like other children of their age. The onset of the disease was insidious, and the first definite symptom was "lameness" in the lower extremities. There is now flaccid paralysis below the knee and spastic paralysis above it. With assistance they can stand up; they sit propped-up in a chair most of the day. Ulcers appeared on the legs and feet and still occur frequently, but they heal well, as a rule. In the case of two brothers, no edema of the legs has been observed during the last two years. They both showed pes equino varus; the leg muscles show atrophy, more marked on the right side than on the left. The anterior aspects of the legs and dorsum of the feet have areas of glossy skin and pigmented scarring of healed ulcers. In the woman, there is considerable edema of the feet, pitting on pressure; owing to the edema, the presence of any atrophy of muscles cannot be made out. The woman also has scars of ulcers. The patients all show atrophy of the small muscles of the hand. This is most marked in the woman, who also has wasting in the distal part of the forearm. Blueness and cyanosis of the legs below the knees, and, in the woman, below the elbows, rapidly develops when the extremities are in a dependent position for a short time. The patients are fatuous and childish in many respects. Their intellect is very poor, and answers to questions are very often erroneous. There is also wasting of the muscles below the knee and the small muscles of the hands, especially the thenar and hypothenar muscles, and paralysis of the muscles of the leg and foot. The knee cannot be bent because the muscles of the thigh are spastic. Some spasticity of the hands is also present. Muscular coordination is not impaired. Fibrillary twitchings occur in the muscles of the thigh, in the thenar and hypothenar eminences, and in the temporal and masseter muscles. Peronei of the right leg do not respond to the faradic current; all other muscles of the legs do.

Conditions Necessary to Arouse Allergic State in Tuberculosis; Immunity Through Fixation of Bacteria. A. K. Krause,—p. 29.

Combating Tuberculosis in Denmark.—In 1905 the Danish Rigsdag passed the Danish Tuberculosis Acts which, through the very comprehensive provisions regarding state grants, rendered it possible to introduce an extensive attack on the disease. Isolation and treatment in hospitals of patients suffering from tuberculosis were made the chief points. Owing to the extensive provisions of state grants provided under the Danish Tuberculosis Acts, it was rendered possible to found a sufficient number of hospital beds, partly in sanatoriums erected by means of considerable grants-in-aid from the state in connection with considerable contributions provided through the intense efforts of private individuals, partly in tuberculosis hospitals built by the municipalities, and also by means of state grants. Every person suffering from tuberculosis and without means can be treated free of charge, and in the case of destitute persons the municipality further has to contribute to the support of the family as long as the breadwinner is under treatment in hospital or sanatorium. In addition the tuberculosis acts contain very comprehensive provisions in other directions, of which the following should be specially noticed: (1) obligatory notification of all cases of pulmonary or laryngeal tuberculosis; (2) disinfection, free of charge, on deaths due to tuberculosis, or on removal of a patient suffering from tuberculosis; (3) examination, free of charge, of sputum, in order to verify tubercle bacilli; (4) education, free of charge, of children suffering from pulmonary tuberculosis, in special departments or schools; (5) definite provision as to grant-in-aid from state and municipality for the working expenses of tuberculosis stations (dispensaries). In 1922, 4,907,400 gold francs were appropriated for this work. At present there are seventy-two tuberculosis institutions with 3,458 beds. In 1900, before this act was in force, there were twenty-three deaths per 10,000 population. In 1923, there were 9.6 per 10,000 population.

Localized Form of Achondroplasia. R. Porak.—p. 179.
*Sugar in Cerebrospinal Fluid. Fontanel et al.—p. 186.
*The Hemotonia Factor in Sedimentation Test. Balachowsky.—p. 201.
Development of the Nervous System. J. Lhermitte.—p. 209.

Tabes Associated with Osteitis Deformans.—Guillain and Péron point to their case, in a man, aged 54, which may confirm the syphilitic origin of certain cases of Paget's disease. The spontaneous fracture of the femur in their case might be ascribed to the tabes as well as to the osteitis deformans.

Diagnostic Value of the Sugar Content of the Cerebrospinal Fluid.—Fontanel, Leulier and Rouquier conclude from 350 tests of the cerebrospinal fluid that a reduced amount of the sugar may help in differentiation of tuberculous meningitis from epidemic encephalitis in which the sugar is usually increased. No diagnosis can be based on an exaggerated sugar content since this may be encountered in normal subjects as well as in various pathologic conditions.

The Hemotonia Factor in the Sedimentation Test.—Balachowsky applies this term to express the elasticity of the erythrocytes. The less the elasticity, the lower the upper surface of the sediment.

*Basal Metabolism During Fasting. M. Labbé and H. Stévenin.—p. 631.
*Roentgen Rays and Gastric Secretion. P. Brocq and P. Oury.—p. 644.
Functional Stomach Tests. S. Cytronberg.—p. 664.
Compensation in Small Intestine After Colectomy. A. G. Weiss and P. Porcher.—p. 692.

The Basal Metabolism in Prolonged Fasting.—Labbé and Stévenin's research was made on a man, aged 42, voluntarily fasting for forty-one days. Their findings as well as those of several other authors in fasting subjects showed a decrease of the respiratory metabolism. The loss of weight was less in the subject in whom reduction of the metabolism was more pronounced. This fact and the increased metabolism with overeating prove the adaptation of the organism to the intake of food. Evidently the functioning of the endocrine glands is not exclusively responsible for the basal metabolism rate.

Action of Roentgen Rays on Gastric Mucosa.—Direct exposure of the gastric mucosa to roentgen rays in Brocq and Oury's experiments showed that the lesions from the rays were circumscribed and comparatively insignificant, even with doses far superior to those ever used in therapeutics. This fact, the authors say, suggests that the roentgen rays may become in the future an effectual and harmless method of treatment for stomach disease in man. They irradiated the mucosa through a stomach fistula (dogs) giving 500 R unit doses at a time, up to a total of 7,000 R units (Solomon ionometer). Secretion fluctuated at first then declined.

Bulletin de l'Académie de Médecine, Paris

94: 917-940 (Oct. 27) 1925

*Remote Results of Sympathectomy. T. Jonnesco.—p. 919.
Monosodium Citrate in Therapeutics. R. Blondel.—p. 931.
*Change of Air in Whooping Cough. Barbary.—p. 936.

Heart Functioning After Sympathectomy.—Jonnesco reports cases which, he thinks, prove that sympathectomy is not dangerous, while it is the only effectual operation for angina pectoris. He has collected seventy-four cases in which different methods of sympathectomy were applied; the mortality was about 20 per cent. in all. His cervicothoracic resection was applied in thirty-two cases; in twenty-four, partial cervical sympathectomy (including resection of the stellate ganglion), and resection of the depressor nerve, in eighteen. One man, operated on for angina pectoris nine years before, keeps an employment requiring physical strain, much walking, without any disturbance of the heart. In another a bilateral sympathectomy was made three years ago, and the man still works as a woodcutter. Still another, submitted to a total sympathectomy for exophthalmic goiter twenty-one years ago, served as a soldier in the active army during the war. Two girls treated by bilateral sympathectomy twenty-five years ago, for epilepsy, are at present mothers of six and seven children. No disturbances of the heart appeared during their repeated pregnancies. Left cervicothoracic sympathectomy was applied ten months ago in a man with severe angina pectoris. There has been no recurrence of the attacks of angina pectoris and the condition of the heart is good, notwithstanding severe occupational strain. He reaffirms that the stellate ganglion should be the main point of attack.

The Change of Air Tradition in Treatment of Whooping Cough.—Barbary ridicules the popular belief that change of air may check whooping cough. The only effect from transporting a child with whooping cough from one place to another may be the spread of the disease, and therefore it should be strictly forbidden.

Bulletins de la Société Médicale des Hôpitaux, Paris

49: 1339-1368 (Oct. 30) 1925

*"Hemophilia-Hemogenia." L. Babonneix.—p. 1339.
*Parkinson's Disease with Syphilis. Babonneix and Pollet.—p. 1340.
Multiple Affection of Glands or Tuberculous Lymphomas? L. Babonneix and L. Pollet.—p. 1341.

*Tumor of the Frontal Lobe. Lechelle et al.—p. 1347.
The Course of Endocarditis. M. Renaud.—p. 1352.
*Glucose Regulation in Infectious Disease. Labbé and Boulin.—p. 1358.

"Hemophilia-Hemogenia." — Babonneix cites Heberden, who described in 1802 a case of joint disease similar to that in hemophilia, associated with fragility of the vessels manifested by spontaneous appearance of ecchymoses.

Nonspecific Affection of Central Nervous System in a Syphilitic.—Babonneix and Pollet observed a case of typical Parkinson's disease in a syphilitic man, aged 47. The contrast between the strongly positive Wassermann reaction in the blood and the completely normal cerebrospinal fluid indicated that the coexisting paralysis agitans was of nonspecific nature.

Tumor of Frontal Lobe.—Lechelle and his co-workers report two cases in which recurring attacks of somnolency formed the early and predominant symptom. In the first case the narcolepsy developed into coma, simulating epidemic encephalitis; in the other it was followed by progressing hemiplegia. Lumbar puncture and clinical signs revealed intracranial hypertension from a brain tumor. The early narcolepsy had suggested the diagnosis of a tumor located in the infundibulum, or area of the third ventricle. Necropsy showed a glioma of both frontal lobes in one case, and tuberculoma of one frontal lobe in the other.

Derangement in Sugar Regulation in Course of Infections.—Labbé and Boulin applied the alimentary hyperglycemia test in twelve patients with various infectious diseases. During fasting, the glycemia appeared slightly increased. The rise and fall of the glycemia curve was four times longer than usual; the maximum of hyperglycemia increased by 50 per cent. The hyperglycemia triangle was ten times larger, thus revealing an important change of the sugar regulating balance. Alimentary glycosuria was noted in 75 per cent. The disturbance of glucose regulation did not parallel the gravity of the infection; as was shown in cases of typhoid and febrile rheumatism. The impairment of the glucose balance sometimes became more pronounced during convalescence, and persisted for weeks, even months after recovery from the infection. This paradiabetic condition occurred chiefly in young subjects and seemed to disappear completely. No signs of an insufficient functioning of the liver could be detected. It is possible that recurrences of this transient disturbance of glucose balance create a true diabetes more frequently than hitherto believed.

57: *361-396* (Nov. 7) *1925*

Pediatrics in 1925. P. Lereboullet and Saint Girons.—p. 361.
Subcutaneous Injections of Milk. Marfan and Turquety.—p. 377.
Isolated Glandular Lesions After Scarlet Fever. P. Nobécourt and L. Lebée.—p. 385.
*Peptic Ulcer in Children. E. Stulz and P. Woringer.—p. 387.
Masked Congenital Syphilis. P. Lereboullet and J. Brizard.—p. 393.

Peptic Ulcer in Meckel's Diverticulum in Children.—Stulz and Woringer refer to two personal cases and eleven in the literature. The ages ranged from 5 months to 15 years, and the lesion developed exclusively in boys. Profuse intestinal hemorrhage is the first symptom, and also the most constant complication. It is characterized by an unchanged color of the blood, and the tendency to recurrence. The hemorrhage may persist a few days or even weeks, causing grave anemia and death. Perforation of the ulcer occurred in ten of the thirteen cases. Seven died from perforation with generalized peritonitis; one from anemia with localized peritonitis; the remaining five were saved by an operation. They cite the points differentiating this affection from a perforated diverticulitis, intestinal invagination and polyp or tumor of the large intestine. Treatment has to be essentially surgical.

33: 1425 1440 (Oct. 28) 1925

*Skin Reaction to Wine in Gout F Widal et al—p. 1425.
*Ossification of Fractures. R. Leriche and A Policard—p 1426.

Skin Reaction to Wines in Gout.—Tests were made with different wines in nineteen patients, aged from 30 to 72, in various stages of articular gout An intense reaction was manifest in three cases, a slight in thirteen and the response was negative in three The reaction was negative in thirty-nine of forty-four persons, healthy or with another disease Widal and his co-workers emphasize that the sensitization of the gouty patients seemed to be induced always only by one kind of wine

Mechanism of Healing of Fractured Bones.—Leriche and Policard summarize the process of ossification. The traumatic hemorrhage is followed by formation of clots and appearance of embryonal connective tissue Congestion in the area of fracture induces bone resorption and production of calcium salts. The two facts cause ossification, occurring by the sixth to the tenth day. Healing is prevented if one of these factors is lacking.

33: 1441-1456 (Oct 31) 1925

*Polyneuritis with Epidemic Encephalitis Beriel and Devic—p 1441.
*Etiology of Endemic Goiter. A. Ravina—p 1442

"Peripheral" Form of Epidemic Encephalitis.—Bériel and Devic describe two personally observed cases and one of Sicard's with clinically associated phases of epidemic encephalitis and polyneuritis. The virus of epidemic encephalitis can evidently affect the peripheral nerves and roots as well as the meninges. The prognosis of this polyneuritis is favorable; it persists from one to five or six months, but without inducing any notable atrophy of the muscles. The differentiation from acute anterior poliomyelitis may be based on the milder invasion of the disease, and the slower appearance of paralysis. The usual treatment for polyneuritis should be applied in these cases.

Intestinal Virus as Factor in Etiology of Goiter.—Ravina analyzes the different theories of endemic goiter. He believes that McCarrison's experiments on man and animals in India present strong evidence in favor of the etiologic significance of water contaminated with fecal matters from persons with goiter. Although the specific virus still eludes discovery, there is much to sustain the theory of an infectious, intestinal origin.

*Local Spasms of Muscles. R. Bing—p. 993
Roentgen Ray Examination in Accident Cases. G. Baer.—p. 1000. Begun p 975
*"Hystero Epilepsy" E Bleuler.—p. 1005.
*Autoserotherapy in Pleurisy. D. Pometta—p 1005.

Local Spasms of Muscles.—Bing analyzes various tics and local spasms and their relation to hyperkinesis of subcortical origin. He believes that various hysterical symptoms are also directed from these centers. In this case the inhibition exerted by the superior centers on the ontogenetically and phylogenetically older automatic centers is removed by the psyche—not by organic disease, as in encephalitis. He explains the resemblance between the symptoms of a major hysterical attack and those of coitus partly by denying it, partly by pointing out that coitus is the only ecstasy-producing, that is, inhibitions-releasing occasion for civilized people. (Die einzige Gelegenheit bei welcher der gesunde, nuchterne Kulturmensch unserer Zeit noch in "Ekstase" zu geraten pflegt; beim Hysteriker aber vermögen auch andere affektgeladene Situationen Enthemmungsphanomene freizumachen). Bing emphasizes that the effect of psychotherapy does not exclude an organic basis for a disease.

Hystero-Epilepsy.—Bleuler protests against the use of the term "hystero-epilepsy." With the same logic, we would have to call a combination of tabes and tuberculosis, "tuberculo-tabes."

Autoserotherapy in Pleurisy.—Pometta finds that the beneficial effects of autohemotherapy in pleurisy are doubtful. There can be no doubt, however, as to the possibility of inoculating tuberculosis subcutaneously.

Pediatria, Naples

33: 1141-1196 (Nov. 1) 1925

*Diphtheria Immunization with Schick Tests. Ivo Nasso—p. 1141.
*Atypical Malaria in Children. G Macciotta—p 1151.
*Vitiligo and Congenital Syphilis P. Fornara—p. 1170.
Congenital Dislocation of the Hip Joint N. Caprioli—p. 1182.

Diphtheria Immunization with Schick Tests.—Nasso confirmed a weakening of the Schick test if repeated after ten or fifteen days Three or four such tests were sufficient to change the response to negative. Estimation of the antitoxin content in the serum of such children showed that the immunization is real.

Atypical Malaria in Children.—Macciotta points, among others, to a hypothermic form.

Vitiligo and Congenital Syphilis.—Fornara observed nine cases of vitiligo among 3,000 children. Congenital syphilis was certain in four, doubtful in two, and excluded in three of his nine cases Vitiligo may occur also in acquired syphilis.

*Periarterial Sympathectomy. A. Valerio—p. 81.
Case of Epispadias. J R da C. Doria—p 84.
Keratitis in Congenital Syphilis. E Campos—p. 89.

Periarterial Sympathectomy.—Valerio removed the adventitia of the femoral artery for a stretch of 12 or 15 cm. on each side in treatment of bilateral mal perforant The interval between the operations was nearly three weeks. A few days after each operation the trophic ulcers began to bleed and presented an intense inflammatory reaction, then rapidly healing over. The man had a history of malaria and syphilis but saturation with quinin and with arsphenamin had not modified the lesions on the feet. The long rebellious mal perforant on one foot in another case healed over in twelve days In a third case the patient refused to allow the intervention—scoffing the possibility of curing an ulcer on the foot by operating on the thigh—and fatal gangrene soon followed.

2: 123-142 (Sept. 5) 1925

*Tropical Ulcer. P. Mangabeira Albernaz—p. 123.
Digestive Leukocytosis. A. L Pimenta Bueno—p. 127.

Treatment of Tropical Ulcer.—Mangabeira Albernaz has been treating tropical ulcer by different methods but found bismuth the most effectual. He used the acid tartrate-bismuthate of potassium and sodium in sixty-four cases, and states that all pain disappeared by the second to the fourth hour and the lesion cleared up promptly while the fusiform bacilli, spirochetes and other germs were reduced to a half in twenty-four hours. One boy aged 6 had six different ulcers; each was given different local treatment. The one treated with bismuth healed much more promptly than the others One man had an extremely painful ulcer on the foot which had resisted all treatment for two years but healed in seven days under five applications of the bismuth.

*Paroxysmal Hemoglobinuria in Child. Marin and Coutts.—p. 1218.
Dermatoses. Amaury Pasqualis Politi.—p. 1221. C'tn.

Excitability of Tawara's Node.—The tracings from a case of septal bradycardia of presumably syphilitic origin showed block of the Keith-Flack node. The occasional auricle waves preceding the ventricle seemed to start in Tawara's node. Under inhalation of amyl nitrite, the pulse increased to 120, but the auricles did not contract.

Regional Episodes of Fibro-Angiomatosis.—Crops of tumors developed and retrogressed without leaving a trace, each crop accompanied by the symptoms of an acute infection. There were never any chills, and the sudden drop of the temperature to normal was not followed by sweating. No treatment displayed any efficacy except perhaps spleen organotherapy, and this effect was transient. The patient was a woman, aged 30.

Paroxysmal Hemoglobinuria.—In the case described, in a boy, aged 4, with signs of congenital syphilis, the paroxysms of hemoglobinuria were preceded by jaundice. There have been no further attacks since a course of treatment for the congenital syphilis.

The Surgeon and the Problems of Workmen's Compensation Cases. D. Couoh Vásquez.—p. 92.
Pellagra and Vitamins. R. Carrancá y Trujillo.—p. 96. C'cn.

Precocious Menstruation.—Farfán López' patient was a child of 9 with signs of old rickets and the lymphatic temperament, mentally and physically backward. She had been having a menstrual flow for a month and the anemia was extreme. The hemorrhages had resisted the usual hemostatics, but were arrested by thyroid treatment. During the three months since apparently physiologic menses have returned at the normal dates. Ten days before each the thyroid treatment was resumed. The general condition has shown marked improvement.

Semana Médica, Buenos Aires

2: 673-740 (Sept. 17) 1925

*Epigastric Hernia. J. R. Goyena.—p. 673.
*Cancer in Female Larynx. H. Zubizarreta.—p. 680.
Traumatic Diaphragmatic Hernia. Olmos et al.—p. 683.
Treatment of Bronchopneumonia. J. Melfi.—p. 687.
Toxic Edema in Liver Disease. Barilari and Hardoy.—p. 706.
*Treatment of Trachoma. Urrets Zavalia.—p. 708.
Relations Between the Semicircular Canals and the Movements of the Eyes in Man. E. Adrogué.—p. 718.
*Labyrinthitis from Traumatism. J. Basavilbaso.—p. 724.

Gastric Disturbance with Epigastric Hernia.—Five years of constipation alternating with diarrhea, pains in the stomach not connected with meals, tenderness in the pylorus region, and signs of overexcitability of the parasympathetic nervous system were all explained by a tender reducible epigastric hernia. Strauss has reported four cases of coexisting epigastric hernia and gastric ulcer. If symptoms persist after surgical correction of the hernia, with apparently normal conditions in the stomach, treatment to soothe the overexcitable vegetative nervous system is called for.

Laryngeal Cancer in Women.—Zubizarreta's experience indicates that cancer in the larynx is less malignant in women than in men. Deep roentgenotherapy has apparently cured completely in his one case in a woman.

Subconjunctival Injections of Copper Sulphate in Treatment of Trachoma.—A 1 per cent. solution with 4 per cent. procain was injected, and 58.3 per cent. of forty-eight patients were cured, and others, to a total of 83 per cent., were more or less improved. Corneal ulcers healed more rapidly than with any other treatment. Nicati's technic was followed.

Diffuse Labyrinthitis from Foreign Body.—The efforts to dislodge a grain of corn in the boy's ear drove it farther in. It was extracted the sixth day by a petromastoid operation, the child having presented symptoms of diffuse labyrinthitis in the interim. The corn was in three pieces; this testified to the force that had been applied in the efforts to extract it, which explained also the pus in the middle ear.

Appendix in Hernia. E. L. Vila and G. F. Nunes.—p. 791.
Summary of Kinetic Plasmogenesis. A. Mary.—p. 809.

Measles.—Liceaga states that the official 23.5 per cent. of mortality from measles in Buenos Aires (1924) is below the reality because the deaths are often credited to the complicating pneumonia or other disease. He comments favorably on vaccine treatment, and advises diphtheria antitoxin with laryngitis in measles, and local measures to abort complications. Fourteen children that had been exposed to measles were injected with convalescent serum and none developed the disease.

Persistence of Implanted Thyroid.—Twelve years after intra-abdominal implantation of a piece of the thyroid gland, Eiselsberg found a tumor of the structure of an adenoma of the thyroid. The normal tissue of the implant had probably been resorbed, and the adenoma tissue had proliferated.

Early Diagnosis of Tetanus.—Buzello injects a suspension of the wound secretion from the patient, subcutaneously, in white mice or other animals. The initial symptoms of tetanus (unilateral or paraplegic rigidity) are characteristic within twelve to twenty-four hours.

Functional Tests of the Circulation.—Frey recommends Kauffmann's diuresis test in surgical patients.

Etiology and Treatment of Megacolon.—Brüning regards megacolon as a congenital—sometimes inherited—malformation (partial gigantism). It is due to the absence of inhibiting impulses from the vegetative nerves. Some abnormal condition of the vegetative centers of the spinal cord is probable, he says. Mechanical and functional disturbances complete the pathologic development. Resection is the best treatment. He removed in one case 216 cm. of the large intestine.

Resection of Colon in Constipation.—Finsterer has resected the colon in thirty-six cases of chronic constipation. The first cases were operated on because of a volvulus. He prefers resection of the left half of the colon—even in the so-called ascending type of constipation He recommends the method not only in elongation of the colon, but also in spastic constipation, when it resists other treatment and causes pains

Denaturing of Alcohol.—Perthes found that all the compounds allowed in Germany for denaturing of alcohol make it unsuitable for surgical disinfection of the hands. He offered a resolution to appeal to the authorities to allow the use of the Swiss method (addition of 1 5 per cent. of acetone). The motion was carried.

Bacteremia After Operations.—Seifert reports on the frequency of bacteremia after surgical interventions. It occurred after nine out of his forty-three appendicitis operations Although it has not much practical importance, it would be better to prevent it by cautious manipulation and, perhaps, by blocking the focus

Healing of Fractures.—Schubert found that crushing of the bone is followed by a more rapid new formation of bone and consolidation than a simple fracture. This is due to the stronger proliferation of capillaries in the former case

Surgery of Acute Osteomyelitis.—Hedri found lipuria in the grave cases of human and experimental osteomyelitis. Only these cases need immediate opening of the bone Incision of the subperiosteal abscess is sufficient in the others.

Dislocation of the Radius in Children.—Bonn found no excessive growth in length of the radius in cases in which there had been untreated dislocation of this bone in childhood. With a rupture of the annular ligament, necrosis of bone occurs Yet this does not entail a deforming arthritis - probably because of the absence of pressure on the joint.

Epidemiologic Research.—Prausnitz deals with Wolter's attempt to revive Pettenkofer's theory. He admits that the present knowledge of epidemiology is not complete. Nevertheless much has been cleared up, and for the rest he prefers the theory of changes of virulence of the germs.

"Reizserum" from Syphilitic Infants.—Soldin and Lesser produced by cantharidin blisters in infants. They found spirochetes whenever there were cutaneous manifestations of syphilis This was valuable in cases with a negative Wassermann test. Mercuric chlorid and potassium permanganate killed the spirochetes. Addition of a Wassermann positive serum or of a serum taken immediately after injection of arsphenamin had no influence. No spirochetes were found in new blisters after injection of arsphenamin in the children although those remaining in old blisters were not injured.

Action of Proteins on Ketonuria.—Thannhauser and Markowicz administered various amino-acids to patients with grave diabetes. Even leucin, phenylalalin and tyrosin did not increase the ketonuria on low caloric diets. The influence was, however, distinct with diets high in calories. They believe that proteins are ketonogenous only in proportion to their content in these amino-acids Yet since the rest of the protein is converted into sugar, the patient catabolizes the proteins and fat of his body, which raises the ketonuria indirectly. They find that the formation of acetone bodies is evidence of disturbed oxidation of sugar as the primary change in diabetes The oxidation of sugar in the muscles does not disprove this It is an entirely different process from the oxidation in the liver The glycogen in the muscles, or at least its synthesis and cleavage, may also be different. The disturbance of the utilization of sugar is localized in the liver, and entails consecutive disturbances of the utilization of proteins and fats.

Acroparesthesias. — Straus and Guttmann divide their eighty-seven cases of acroparesthesia into two groups: One occurs in individuals between 20-40 years of age and is connected with vasomotor symptoms (cyanosis, white color or edema of fingers). This group is a vasoneurosis. The other type resembles tetany pathogenetically; occurs in the menopause, and presents an exaggerated electric and mechanical irritability of the nerves. Vasomotor symptoms do not occur here

Endocrine Glands in Pernicious Anemia.—Mendershausen found the pituitary, pancreas, suprarenals and gonads practically normal in his thirteen cases of pernicious anemia. He found, however, in twelve of them changes in the thyroid gland (lymphocytic infiltrations with atrophy, occasionally increase in colloid).

The Interbrain in Pemphigus.—Buschke and Ollendorff report a case of pemphigus in which Bielschowsky found hyperemia and grave cellular changes in the nucleus paraventricularis

Gas Metabolism in Exophthalmic Goiter.—Pollitzer and Stolz found that the product of the basal metabolism and percental increase of metabolism after intake of proteins (specific dynamic action) is a constant in normal conditions and in those cases of increased basal metabolism in which the increase is due to changes of central regulation (fever and asthma). This means that an increased basal metabolism causes a lowering of the specific dynamic action. Calculated on a basal consumption of 3 to 4 c.c. of oxygen per kilogram and of a specific dynamic increase of 16 per cent., the constant ("gas metabolism index") would range from zero to 70. It is normal in simple goiter with toxic symptoms, and increased up to 200 in the classical exophthalmic goiter, progressive iodin poisoning and iodin hyperthyroidism. Iodin therapy is contraindicated in the first group. Besides this it is contraindicated in patients who have a high index due only to an excessive specific dynamic action (30 per cent.) in spite of a low basal metabolism. On the other hand, it is indicated in the second group and with nodular goiters which have lost their colloid, in spite of a low index.

Insulin and Tar Cancer.—Witzleben tarred three groups of four rabbits. The small wartlike precancer lesions appeared in five weeks in the first (control) group; in nineteen days in the second (injected with epinephrin and glucose), and so far not at all in the third group, injected with insulin.

Epidemics in 1924. B. Möllers.—p. 1670.

Hygiene of the Ear.—Ruttin warns against cleaning of the meatus with swab and water. It only increases the amount of cerumen. The cleaning or scratching of the ear with hair pins or matches causes eczema and furunculosis. A kiss on the ear easily ruptures the drum-head, as also a slap on the ear. Cotton soaked in oil should be applied before swimming, especially in persons with perforation of the drum-head. The oil soaked pledget prevents infection as well as rupture of the membrane in diving. The infections of the middle ear, due to blowing the nose with both sides closed, are frequent. Noise is an important factor in disease of the internal ear. He observed two deafmute children with no other cause for the deafmutism except the noise of their father's smith-shop, where they were kept during the day, while they were infants. The younger the start in such noisy industries, the graver the injury to the ear. The parenchymatous keratitis beginning at the age of 10-14 in congenitally syphilitic children is usually followed within a year or two by the affection of the internal ear.

Pneumococcus Peritonitis.—Wolfsohn observed seven cases of pneumococcus peritonitis. The condition is usually attributed to appendicitis. Early operation is frequently fatal; the prognosis with late operation is good. Application of ether after lavage of the peritoneum can be recommended.

Agranulocytosis.—Schultz and Jacobowitz have encountered to date ten cases of agranulocytic angina, and regard only thirteen other cases from the literature as belonging in this category. They emphasize the absence of a hemorrhagic diathesis and of thrombopenia, and the practically normal erythropoiesis. They believe in a primary injury of the leukomyeloid apparatus.

Choleresis and the Blood.—Rösler counted the blood for four hours after intravenous injections of a sodium salt of phenylcinchoninic acid in twenty five patients with jaundice. He found a marked lowering of the erythrocytes and increase in leukocytes, especially the neutrophils. He believes that an increased destruction of erythrocytes took place.

Birth Injury.—Wiechers shows that the majority of infants who die in the first days have grave injuries of the brain. The favorite clinical diagnosis in these cases was "premature" or "congenital debility." The same injury causes death in the second two weeks of life, the favorite diagnosis then being atrophy, purulent bronchitis, pneumonia or malnutrition.

Skin Reactions to Rays.—Schwarz found that the secondary latency period is not limited to erythemas due to the action of ultraviolet or roentgen rays. He found the same phenomenon after application of mustard oil on the skin, the only difference being in the speed: hours in mustard oil dermatitis and weeks after the roentgen rays. There is also an analogy in the Pirquet test. He believes that these reactions are manifestations of a tissue allergy.

Advantage of Colon Bacilli in Intestine.—Loew points out that colon bacilli are capable of converting ammonia into proteins, and thus protect the organism against the ammonia.

Bone Changes in Spastic Paralysis.—Rohde found in six of his seven grave cases of Little's disease changes in the bones (three cases) or in the joints. He explains the former by new formation of bone where the contracted muscles have a broad and well vascularized attachment to the periosteum and bone.

Potassium Treatment of Retention of Urine.—Reimer had further good results in postoperative retention of urine. He administers 1-2 tablespoonfuls of a solution of 60 gm. of potassium acetate in 300 gm. of water. In obstinate cases he adds one spoonful every half hour. In 150 cases this treatment proved successful in 64 per cent. (50 per cent. in women; 70 per cent. in men). The remedy is of no use with motor insufficiency of the stomach.

Sympathectomy in Bronchial Asthma.—Rehbein expects success with sympathectomy in those patients with bronchial asthma who experience relief when the cervical ganglions are anesthetized. He found a tenderness in that region in such cases.

"Epidemics, Soil and Climate."—Schilcher traces the epidemic of influenza in Finland exclusively to a shipload of Bavarian soldiers who arrived there in June, 1918.

History of Phrenicotomy.—Hellin claims priority in having demonstrated the futility of phrenicotomy in treatment of pulmonary tuberculosis, as made by Sauerbruch.

Treatment of Itching Dermatoses. G. Nobl. Supplement.—pp. 1-24.

Vienna Water Problems.—Grassberger describes the so far unsuccessful fight of the Hygienic Institute of Vienna and of the public health service against the intended endangering of the purity of the water supply. The chief expert of the opposing party is a geologist whose ignorance and superstitious delusions (divining rod) were shown up in flagranti by the author nine years ago.

Diabetic Glycosuria.—Schur and Kornfeld found that the glycosuria occurs with low blood sugar in true diabetes. They attribute the absence of sugar in the normal urine to its complete oxidation in the kidney. They believe that it appears in the urine in diabetes because the kidney is unable to use it.

Professional Disease and Injury by Electricity.—Jellinek points out that most of the persons seemingly killed by electric currents can be successfully revived. Yet the artificial respiration is frequently done in a way which kills the injured (aspiration of gastric contents in lungs). Electric wounds heal surprisingly well and radical surgery is contraindicated.

Conjugal and Syphilitic Exophthalmic Goiter.—Koopman emphasizes the necessity to think of a syphilitic etiology in exophthalmic goiter. Iodids have a surprising effect in these cases.

Chemotherapy of Tuberculosis of the Skin. G. Nobl.—p. 1190.
Treatment of Goiter, Hyperthyrosis and Exophthalmic Goiter. N. Jagić. Supplement, pp. 1-12.

Action of Diuretics on the Tissues.—Wermer and Zak injected sodium iodid intravenously or subcutaneously. It appeared in the saliva in both instances earlier in women than in men. They confirm Ameuille and Sourdel's observation on the delayed appearance in the saliva in nephritis. Diuretics (theobromin group, urea, novasurol) caused also a more rapid elimination by the saliva. They conclude that these drugs induce a more rapid circulation of the tissue fluid.

Viability of Tubercle Bacilli.—Passini cultivated tubercle bacilli together with *Bacillus putrificus Bienstock*. The tubercle bacilli were killed within nine days.

Anaphylaxis to Echinococci.—Botteri confirms the reliability of tests made with fluid from echinococcus cysts to obtain cutaneous reactions.

Weakness of the Retina. M. Remeš.—p. 1556.
Biologic Testing of Arsphenamin. A. Mládek.—p. 1560.

Roentgen-Ray Study of Ileocecal Region.—Nekula and Šimon studied more than 100 patients with disturbances in the ileocecal region. The appendix had been removed in twenty of them, yet the distress was not diminished. They found a slow evacuation of the cecum in perityphlitis. Twenty-four hours and longer after the ingestion of a contrast meal the lower part of the cecum was still filled. A spasm of a cecocolonic muscular ring was observed several times. Atropin relieved the stagnation in these cases. A motor insufficiency of the distal part of the ileum may cause gaping of the ileocecal valve. Organic processes such as adhesions and abscess can be studied roentgenologically. A filling of the appendix speaks for chronic appendicitis only if the appendix is tender on pressure. If conservative treatment fails, they recommend appendectomy, severing adhesions and eventually fixation of the hepatic flexure. Fixation of the cecum would only aggravate the condition, if the hepatic flexure were still free or displaced downward.

Resection of Liver in Cancer.—Haim resected successfully a lobe of the liver infiltrated by a cancer of the gallbladder. He emphasizes that metastasis involving only one lobe of the liver does not contraindicate a radical operation on a cancer of the gastro-intestinal tract.

Influence of Iodin on Rats.—Mačela added 0.2 mg. of sodium iodid daily to the food of young rats. They gained in weight faster than the controls, and showed a rapid sexual development.

An Insulin Which Does Not Cause Spasms.—Mačela obtained by a modification of the Dodds and Dickens method a fraction of insulin which lowers the glycemia extremely but does not cause convulsions.

*Wassermann Reaction in Paroxysmal Hemoglobinuria. Salén.—p. 558.

Cancer and Diet.—Hindhede was struck by the high incidence of cancer in Denmark (151 deaths per hundred thousand inhabitants in 1915). Fully 17 per cent. of the persons who have completed their forty-fifth year die of cancer in Denmark. He attributes this to the excellent and more than sufficient food which prevails there. The English farm laborers, with their low protein fare, have a very low death rate from cancer. That of physicians is much higher. He believes that irritation of the digestive tract by decayed, strongly salted and spiced food, alcohol, tobacco, overeating and a food rich in animal protein are the main causes of cancer.

Wassermann Reaction in Paroxysmal Hemoglobinuria.—Salén found that the hemolytic amboceptor causing the Donath-Landsteiner reaction is of no influence on the Wassermann reaction in paroxysmal hemoglobinuria.

VOL. 85, NO. 25 CHICAGO, ILLINOIS DECEMBER 19, 1925

END-RESULTS OF OPERATION FOR CORRECTION OF DROP-FOOT *

WILLIS C. CAMPBELL, M.D.
MEMPHIS, TENN.

Drop-foot is the inability to dorsiflex the ankle joint or foot, and is the result of any agent that impairs or abolishes the muscular power in the anterior group of leg muscles. The etiologic factors are: destructive changes in the muscles and tendons, toxic neuritis, as in lead poisoning, trauma to the external popliteal nerve, spastic paralysis and, most frequently, poliomyelitis, or infantile paralysis. Drop-foot may be simple, when only the anterior muscles of the leg are involved, or it may be associated with varus, valgus or flail-foot, if loss of muscle power is more extensive. As the anterior muscles of the leg are more frequently paralyzed than any other muscle group as a sequela of poliomyelitis, inability to dorsiflex the foot is a very common disability.

In June, 1923, I [1] described before the American Orthopedic Association a surgical operation for the correction of drop-foot in connection with other procedures in which drop-foot is associated with lateral deformities, as varus or valgus. At this time, the method had been employed in twenty-four cases, and only eleven months had elapsed since the first operation; in consequence, definite conclusions could not be reached, but from the evidence offered by roentgenologic and clinical manifestations there was no doubt that the purpose had been accomplished in a limited number of cases. Since the preliminary report, the technic, as originally defined, has been used in 119 cases, making a total of 135, and approximately three years has elapsed since the first operation. In consequence, sufficient evidence has been acquired to determine the real value of the new method.

All operative procedures, with the exception of the one under discussion, attempt to suspend the foot from the anterior aspect of the leg by silk cords, paralyzed tendons, transplanted fascia lata, etc., but the result of such methods is uncertain and often disappointing, as the constant force of gravity by the pendulous foot causes elongation of the improvised ligaments, with recurrence. It has become so universally recognized as to be an axiom that paralyzed tendons will not permit stress. In 1920, the American Orthopedic Association appointed a committee to investigate the various surgical procedures commonly employed in the treatment of paralytic feet. This committee, after a most painstaking, scientific and impartial investigation of the results, demonstrated in a majority of large orthopedic clinics of America, filed its comprehensive report before the association in June, 1921, in which it stated regarding drop-foot: "None of the operative methods considered can be confidently recommended as a standard procedure." After considerable experience and observation of results in other clinics, I reached the same conclusion; in consequence, I instituted a careful investigation to find a more dependable method. This culminated in devising the procedure described below. The entire object of this operation is to construct a stop joint, by transplanting or building up a mass of bone on the superior surface of the os calcis, thus forming a permanent bony process limiting plantar flexion by impingement on the posterior surface of the tibia. The technic is as follows:

The skin incision is made over the Achilles tendon, if this structure is contracted; otherwise to the outer or inner side, as convenient. It should extend from the superior aspect of the tuberosity of the os calcis upward for three or four inches in a straight line. If the Achilles tendon is contracted, a severance is made by the Z plastic method. A straight incision is next made in the midline to the posterior portion of the ankle joint, retracting inward the tendon of the flexor longus pollicis. With a heavy periosteal elevator, a pyramidal space is cleared, exposing the posterior surface of the tibia, ankle joint, subastragalar joint and superior surface of the os calcis. The foot is dorsiflexed, bringing into view the posterior extremity of the astragalus, which is removed for from one-half to three-fourths inch. A wedge-shaped cavity is excavated on the os calcis, below the posterior extremity of the astragalus and the posterior portion of the articular surface of the tibia. Bone is next transplanted from any portion of the skeleton. As it is usually necessary to enter the forefoot for the purpose of stabilization by arthrodesis, bone is often excised in the process, and can be utilized as transplants. Spongy bone is believed more naturally to adapt itself than dense bone from the tibia, though a tibial transplant was successfully employed in one case and has been recently advocated by Leo Meyer. Transplants from the femur, when the case is complicated by genu valgum, and from the ilium, in transferring the crest in hip flexion contractures, have proved efficient. If bone is excised from the forefoot, it is denuded of cartilage, and a large piece about one-half by one inch in diameter is selected and placed in the cavity prepared on the superior surface of the os calcis, about which small particles are arranged in a pyramid. The cartilage removed is placed in mosaic fashion to cover the posterior, inner and outer aspects of the pyramid, to prevent adhesion to surrounding structures; this step, however, is by no means essential, as

[1] Campbell, W. C.: Operation for Correction of Drop-Foot, J. Bone and Joint Surgery 5: 815-825 (Oct.) 1923.

the results are as good when bone is obtained elsewhere, free of cartilage. The soft parts are sutured snugly to retain the transplants in situ, the Achilles tendon is united, if severance is required, and the fascia and skin are closed. The foot is then held by a plaster cast at an angle of 90 degrees with the leg. Overcorrection is especially avoided, as it is preferable to secure a slight degree of plantar flexion, in order to avoid flat sole or heel walking. At the end of eight weeks, the cast is removed and a roentgenogram made, which usually demonstrates proliferation. A sequence of roentgenograms exhibits a gradual organization of bone, until there is a solid mass continuous with and forming a part of the os calcis and often fusing the os calcis to the astragalus, stabilizing the subastragalar joint. Plantar flexion is thus prevented, as the olecranon process limits extension of the normal elbow. The technic may be modified, when the forefoot is stable, by turning forward the upper third of the os calcis, when, incidentally, it is possible to do a subastragalar arthrodesis, or even the horizontal section of Davis, with backward displacement of the foot by the posterior route. It is also possible to transfer particles of bone from the midtarsal region through the subastragalar joint to the superior surface of the os calcis, in performing a triple arthrodesis, but the block cannot be so accurately placed as when the posterior incision is employed.

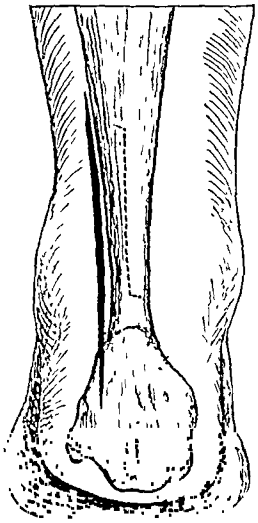

Fig. 1.—Skin incision for bone block operation.

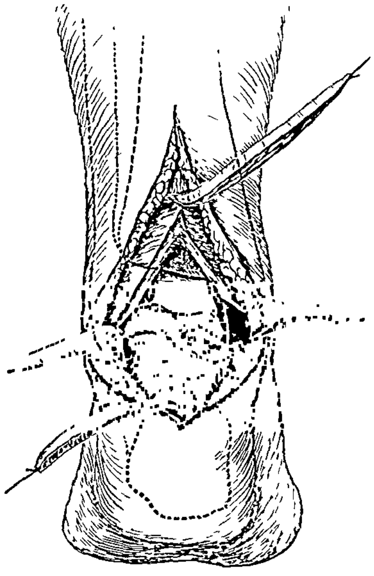

Fig. 2.—Pyramidal space showing superior surface of the os calcis and posterior aspect of ankle joint.

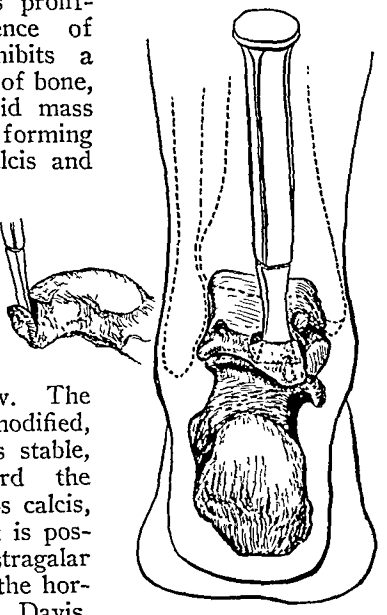

Fig. 3. — Large piece of bone selected to be placed on upper surface of os calcis.

Great care must be taken to place and to retain the bone block approximate to the ankle joint and the posterior surface of the tibia. Displacement is avoided by an apparatus that prevents plantar flexion. Consolidation is usually complete by the end of six months, when the apparatus may be discarded.

The scope of the procedure is apparently not fully appreciated, though it was mentioned in the first report. The operation is not alone employed in simple drop-foot, but whenever drop-foot is associated with other paralytic deformities. The indications are as follows:

1. Simple drop-foot, as a result of paralysis of the anterior group. The midtarsal joint is usually abnormally lax and requires stabilization, which necessitates the excision of bone that may be utilized as transplants.

2. Partial drop-foot, as evidenced by from 25 to 50 per cent. of normal power, but not sufficient to dorsiflex normally. If the midtarsal joint is stable, the bone block may be accomplished by turning forward a flap from the os calcis.

3. Rigid equinus. In this condition, the anterior group is partially, if not totally, paralyzed. Permanent limitation of plantar flexion prevents strain and increases endurance.

4. Equinovarus. The varus is corrected by tarsectomy, when sufficient bone is obtained for transference.

5. Equinovalgus. In this condition, with paralysis of the anterior muscles, a tarsal resection is often indicated, and from it sufficient bone for transference is available.

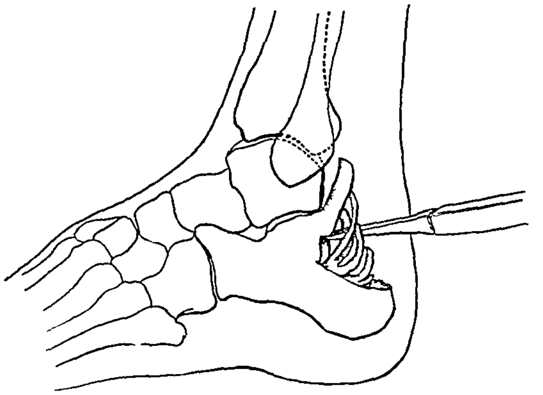

Fig. 4.—Diagram, side view, showing bone block in position approximate to and within ankle joint.

6. Flail-foot. As an addition to the Davis, Dunn, Ryerson or Hoke procedures, the transplant described above makes certain perfect stabilization. Backward displacement of the foot at the subastragalar joint will limit plantar flexion at times, but is not dependable.

7. As an adjunct of various combinations of tendon transference, especially the reattachment of the extensor longus digitorum to the tarsal region.

8. Spastic paralysis, or hemiplegia, with overactive heel cord. In such conditions, recurrence of deformities are notably frequent.

9. In children over 8 years of age. Prior to this time, stabilization operations are rarely indicated.

In fact, it is quite apparent that the procedure has been of value in practically all paralytic deformities of the feet with the exception of cavus, calcaneus and calcaneovalgus. The advantages of the operation are:

1. It has simplicity, as the transplants are usually available from associated procedures.

2. Apparatus may be discarded, as an internal brace is constructed.

3. Muscle power is conserved, by preventing the constant pull of the pendulous foot by gravity.

4. Constant prevention of overstretching may of itself induce a return of dormant muscle power.

5. As functional demands are decreased, feeble power may be cultivated.

6. Rocker motion of the ankle joint is conserved.

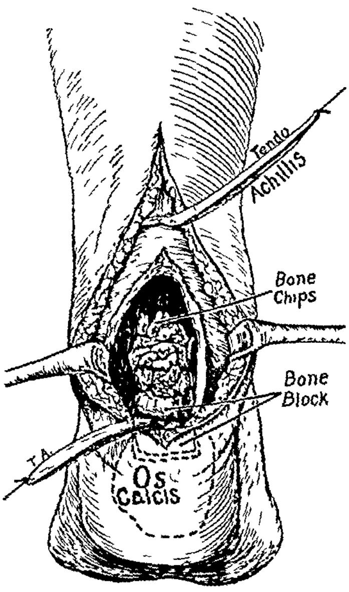

Fig 5.—Modification, which has proved satisfactory in a number of cases, by simply turning up a large flap from the os calcis

The operation has been employed in 135 cases, in 100 of which sufficient time has elapsed to determine permanent results; but no evidence, unless acquired by examination of my colleagues or myself and corroborated by the roentgenogram, is considered worthy of submission. I was so fortunate as to make a survey of sixty-two cases, in which from six months to three years had elapsed since operation. Of the sixty-two patients who presented themselves, there were fifty-eight in whom plantar flexion was satisfactorily restricted by a definite impingement of bone. In four cases, the disability relapsed and these are classed as failures. Of the sixty-two, forty-three were above the age of 14, with only one failure. Nineteen were children below the age of 14 and above the age of 7, with three failures. More time must elapse to determine the effect of growth on the relation of the new osseous process to the ankle joint, but up to the present there has been no evidence of change in position or dissolution, when the end-result was mechanically efficient and was so confirmed by the roentgenogram. However, there is abundant evidence of permanent blocking of joints by fractures occurring in early life.

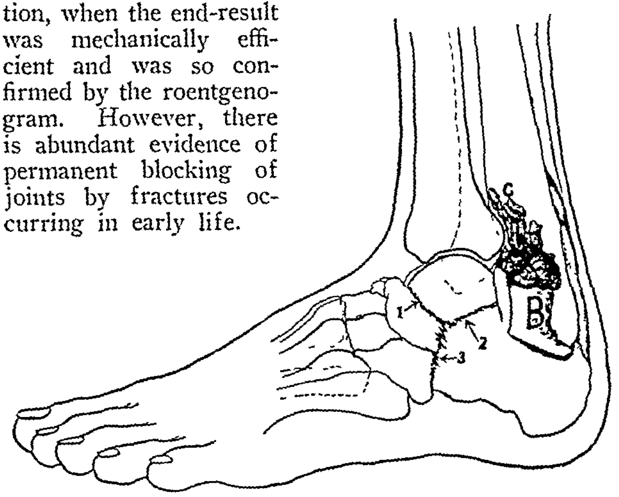

Fig 6.—*B*, bone block; *C*, bone chips, 1, astragaloscaphoid arthrodesis; 2, subastragalar arthrodesis; 3, calcaneocuboid arthrodesis.

In all patients above the age of 14 in whom the result was demonstrated as satisfactory at the end of six months, there can be no question as to permanence. Of the four recurrences, there was absorption of the transplanted bone in one child, while three are attributed to errors in technic, which the roentgenogram clearly demonstrates was caused by failure to place or retain the multiple grafts approximate to the posterior aspect of the tibia and ankle joint.

Persistent pain on walking occurred in two cases; this was probably caused by the transplanting of an excessive amount of bone, but required no treatment, as there is a condensation with contracture as organization is instituted. Should pain persist, a portion of the new process could be removed. One patient complained of sudden pain with swelling; in his case the roentgenogram demonstrated a fracture of the tip of the new process, but recovery was uneventful, without treatment.

There is no intention to convey the impression that the operation is a panacea for all paralytic feet. Many factors, which must be duly considered, are involved in selecting suitable procedures for individual cases. However, the bone block operation to control drop-foot can be recommended with impunity as a dependable surgical procedure which has stood the test of time and from which satisfactory results may be expected in a high percentage of cases, if the original technic is closely followed.

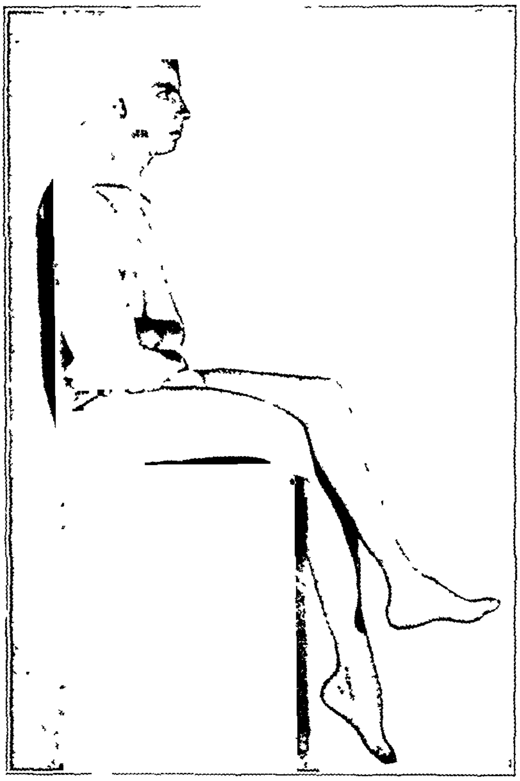

Fig 7.—Satisfactory bone block one year after operation in boy, aged 16. The bone block should be compared with the left foot in extreme plantar flexion.

869 Madison Avenue.

ABSTRACT OF DISCUSSION

Dr. M S Henderson, Rochester, Minn.: I have followed Dr. Campbell's operation from the first. I had the opportunity of seeing a number of these cases and noting the end-results We have all tried to correct drop-foot by silk ligaments, tenodesis, Gallie's operation, etc., and our percentage of failures has been entirely too great. We have all had the experience that Dr. Campbell mentioned of having the foot corrected by the various procedures, but seeing the patient a year or so later with the foot dropped down again. I think that Dr. Campbell's presentation is convincing. The roentgenograms show his results, and, as stated, I have seen his cases and know that the operation does what it is intended to do; that is, it prevents the foot-drop. Dr. Campbell mentioned the procedure being used in spastic paralysis. That is interesting. I wonder how it will work out, and I should like to ask Dr. Campbell if he has had many cases of that kind. The operation must be done carefully. The technic must be correct. It is one of these operations which are not difficult, but still the technic must be strictly adhered to if we want to get results.

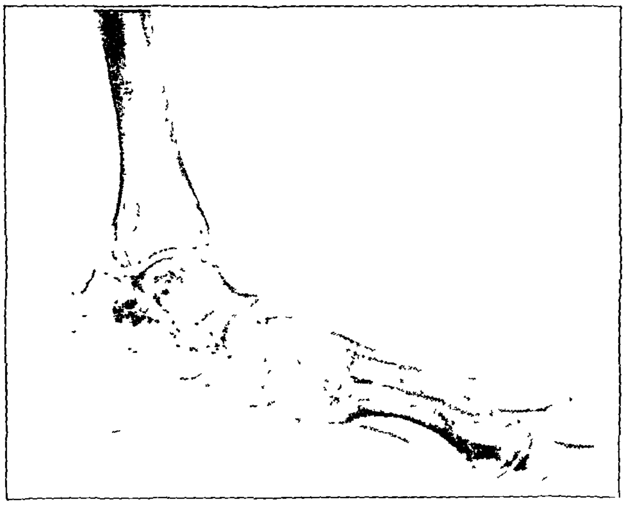

Fig. 8.—Pyramid of transplanted bone posterior to ankle joint, three months after operation.

Dr. M. N. Smith-Petersen, Boston: Dr. Campbell states that the operation has stood the test of time. I do not believe four years is sufficient time to judge the operation by. No weight bearing joint in the body normally has a bony block limiting its range of motion. Any joint that has a bony block as the result of a fracture as a rule sooner or later becomes painful. Dr. Campbell did not make any reference to postoperative pain. If there is no pain during the early postoperative stages, there is apt to be pain in the course of years because of the prolific changes resulting from the constant irritation at the point of impingement.

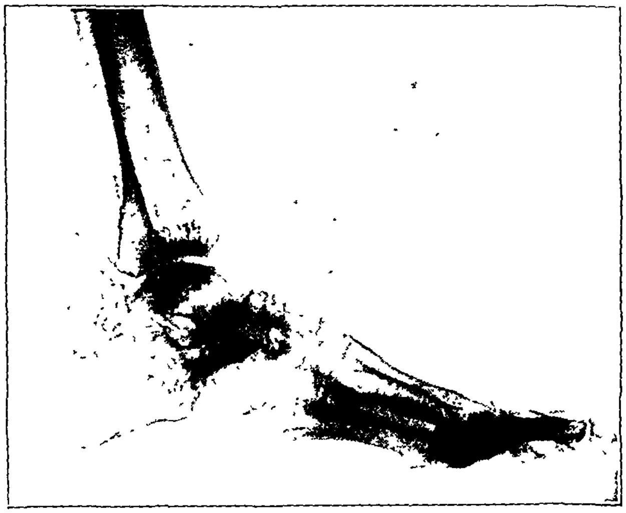

Fig. 9.—End-result eighteen months after the operation, with the bone block within the ankle joint and impinging on the posterior aspect of the tibia; fusion of graft of the subastragalar joint may also be noted.

Dr. W. G. Stern, Cleveland: On behalf of the Foot Commission of the American Orthopedic Association, whose work Dr. Campbell mentioned in his paper, I wish to state that as far as I know the sentiments of the other members of the commission, they agree with the opinion expressed by Dr. Campbell: that no arthrodesis operation on the tibio-astragalar joint is indicated in any condition in which it can possibly be avoided. The original operation of this kind was proposed by Goldthwaite many years ago to cure drop-foot, and his idea was again rejuvenated by Dr. Steindler in an operation he speaks of as panarthrodesis. The commission did not have time to investigate enough of Dr. Steindler's cases to express any definite opinion about it, nor did it know of Dr. Campbell's operation, or see a sufficient number of cases of Hoke's operation that had lasted long enough from which to form any definite opinions. But in the opinion of the members of the Foot Commission, the arthrodesis operation on the tibio-astragalar joint should be avoided, because we all know the sad results in walking that will come with a perfectly stiff ankle joint. Whether or not Dr. Campbell's operation will stand the test of time or use, as Dr. Smith-Petersen infers it will not, I do not know. Nevertheless, it is the only type or kind of operation which in my opinion is going to be successful. Out of all the cases of drop-foot treated by Gallie's operation, Peckham's operation or ligament suspension that we learned of or saw, there was only the smallest proportion in which there was anything like a permanent success achieved.

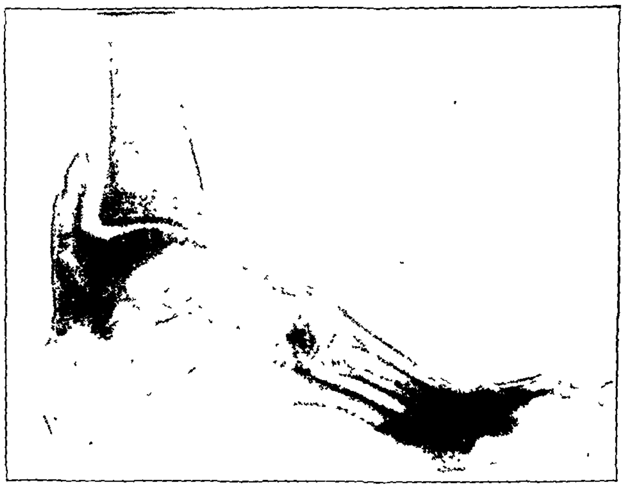

Fig. 10.—Atypical result caused by transplanting an excessive amount of bone. The functional result is excellent.

Dr. J. W. Sever, Boston: A number of years ago when Dr. Campbell presented this procedure for the first time, I discussed it and I objected at that time seriously to it, as it did not seem to me that it was a satisfactory procedure or even a necessary procedure. I am perfectly willing, in view of the results he has reported now, to retract many of the things I said then, and it seems to me, with the exception that Dr. Smith-Petersen cited, that it offers a very satisfactory method for preventing or correcting a drop-foot. At the Children's Hospital in Boston we have been using the Hoke operation for these cases a good deal and have found it extraordinarily satisfactory. There is not much mutilation. There is adequate and excellent correction of the deformity, and, apparently, there is a permanent result without blocking of the motion in the ankle joint. I should like to ask Dr. Campbell whether in putting in this bone wedge he denudes the posterior surface of the tibia of its periosteum, and in the cases in which he operated sufficiently long ago is he able to tell whether there is disability in walking as a result of this bony block, with restriction of motion in the ankle joint, and whether by such insertion of a bone graft he can control either the valgus or the varus deformity.

Dr. P. D. Wilson, Boston: I differ with Dr. Stern that there is no adequate operation for relief of drop-foot. We have all been doing the Hoke operation, and Dr. Sever failed to mention specifically the thing that we try to do in all such cases, and that is to get posterior displacement of the foot, with the excision of the head and neck of the astragalus to a considerable degree, with the loosening up of the os scaphoid joint, with subsequent fusion, but first of all getting the foot displaced well backward so that the heel projects far back. We do exactly the same thing that we do with an astragalectomy; we change the leverage, the long lever in front; we shorten that up and lengthen the posterior lever, and of course that does stabilize the foot not only in the lateral direction but also in the anteroposterior direction.

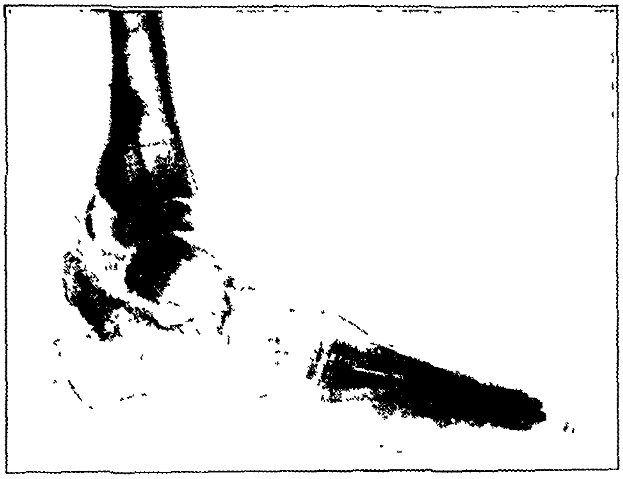

Fig 11.—Bone block accomplished by turning forward upper third of os calcis in boy, aged 6, who had previously had midtarsal fusion

Dr. Albertus Cotton, Baltimore: Has Dr. Campbell had any experience with this operation in adults? I should think the point brought out by Dr. Smith-Petersen is one worthy of attention. I should think there would be danger of later development of hypertrophic arthritis in this particular operation, especially in adults. We know how frequently this condition develops after joint injury in adults.

Dr. Rex L. Diveley, Kansas City, Mo. As an associate of Dr. Frank Dickson, I should like to report a series of twenty-five cases in which the operation just described by Dr. Campbell has been performed These cases we have studied over a period ranging from six months to two years Dr. Campbell's operation has proved very successful. When we first started to use this procedure, we turned down a shelf from the posterior aspect of the tibia; but later we found it was much easier and just as effective to turn a shelf up from the superior aspect of the os calcis, turning this wedge of bone up on the lower end of the posterior aspect of the tibia, and holding it in place by suturing the soft part tightly over this wedge of bone. We have collected a series of roentgenograms of these cases and find that the shelf that was turned up from the os calcis hypertrophies *and forms a stoplock which* does not let the foot drop. We have found it very important in cases of varus or of valgus first to arthrodese the subastragaloid joint, either by a simple subastragaloid arthrodesis or a Hoke operation, generally combining this with a mediotarsal arthrodesis.

Dr. W. C. Campbell, Memphis: In answer to Dr. Henderson, the procedure has been employed successfully in spastic paralysis, but always associated with other measures, such as tenoplasty or Stoeffel's resection for that particular condition. Dr. Smith-Petersen speaks of there being no analysis in nature to the bone block secured as a result of the operation under discussion. In paralysis and many other disabilities a restoration to normal is impossible, and surgery is frequently employed to make as good a substitute as possible —for instance, *there is no analogy in nature to that produced* by his operation for sacro-iliac arthrodesis. I regard three years as sufficient time to determine the result in all above 14 years of age. In young children, as mentioned, the element of growth must be considered in any operation on bone; but there are no epiphyses involved and the results have been satisfactory, as described above. The value of the procedure has been proved to my colleagues and to me. Of course, years *must elapse before any new met*hod becomes an accepted standard procedure. As stated, pain was present in only two adults for a few months but did not persist; however, I have observed continuous pain following astragalectomy and other radical operations, which I am sure has been the experience of others. In answer to Dr. Cotton: There have been no arithritic changes following the bone block operation, nor has there been a tendency to proliferate. As a rule, the multiple grafts contract in fusing, forming a solid mass continuous with and a part of the os calcis. The posterior surface of the tibia is not denuded, as the object of the operation is to limit and conserve ankle motion, not to destroy. In answer to Dr. Sever: Valgus and varus are irrelevant to the subject, and are of interest only when associated with "dropfoot," other well known measures for these conditions being employed. The object of the Davis, Hoke, Dunn and Ryerson operations was first advanced by Davis; namely, a triple arthrodesis with backward displacement of the foot for the purpose of stabilization and the correction of lateral deformities. These measures rarely control anteroposterior motion.

TOTAL AND SUBTOTAL RESTORATION OF THE NOSE *

VILRAY P. BLAIR, M.D.
ST. LOUIS

To be acceptable, a surgically reconstructed nose must be covered with smooth skin, have a normal contour, have an epithelial lining, and provide an adequate airway. Though not always necessary, a rigid support of bone or cartilage will usually add to the quality of the result (Figs. 1 and 2). It is very desirable that the size and form of the new nose be in harmony with the particular face.

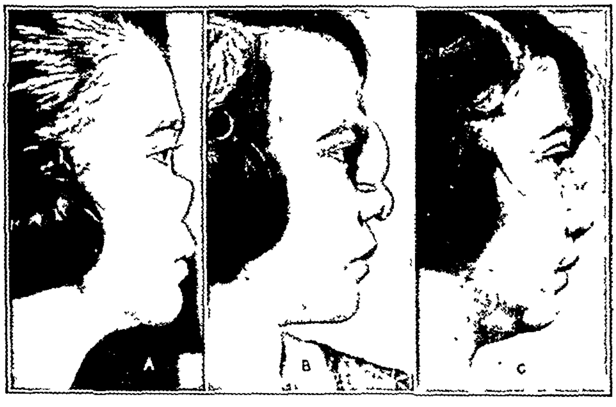

Fig. 3—Lining, tip, columella and upper half of external nose restored by a forehead flap After all scar had been excised and the alae dropped to the normal position, the flap was let in through a transverse incision across the bridge. The raw surface inside was thus lined and the free end of the flap was brought out below and turned into the defect in the tip, leaving enough redundancy in the turn to make the columella. Later the pedicle of the flap was cut across and turned over to make the covering of the upper half. *B*, forehead flap turned in; *C*, completed nose, which contains no supporting framework. This nose would also be better for a cartilaginous bridge. This girl later died of an intercurrent gastric hemorrhage.

Nasal reconstruction amounts to sculpturing with the live tissues for material, and this must be done in conformity with good surgical usage, combined with mechanical accuracy and some artistic feeling (Fig. 3).

* From the Surgical Department of the Washington University Medical School.

* Read before the Section on Surgery, General and Abdominal, at the Seventy Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925

* Because of lack of space, this article is abbreviated in The Journal by the omission of a number of illustrations The complete article appears in the Transactions of the Section and in the author's reprints.

Phidias seems to have been unique among sculptors in his ability to make a free hand carving of his ideal without previously working it out in some plastic material, and there are probably few surgeons of sufficient skill to emulate Phidias' example. Even a tailor will make a pattern before cutting into his cloth. Before any flaps are transplanted, all binding scars should, as far as possible, be removed, and this must be provided for in cutting the patterns (Fig. 5). Having assurance of the patient's physical fitness and of a free air passage (Fig. 4) the first step in reconstructing a nose or any other molded feature is to make an accurate plaster reproduction of the face and then build up the desired feature in clay (Fig. 5); from this, patterns can be made in tinfoil and lead

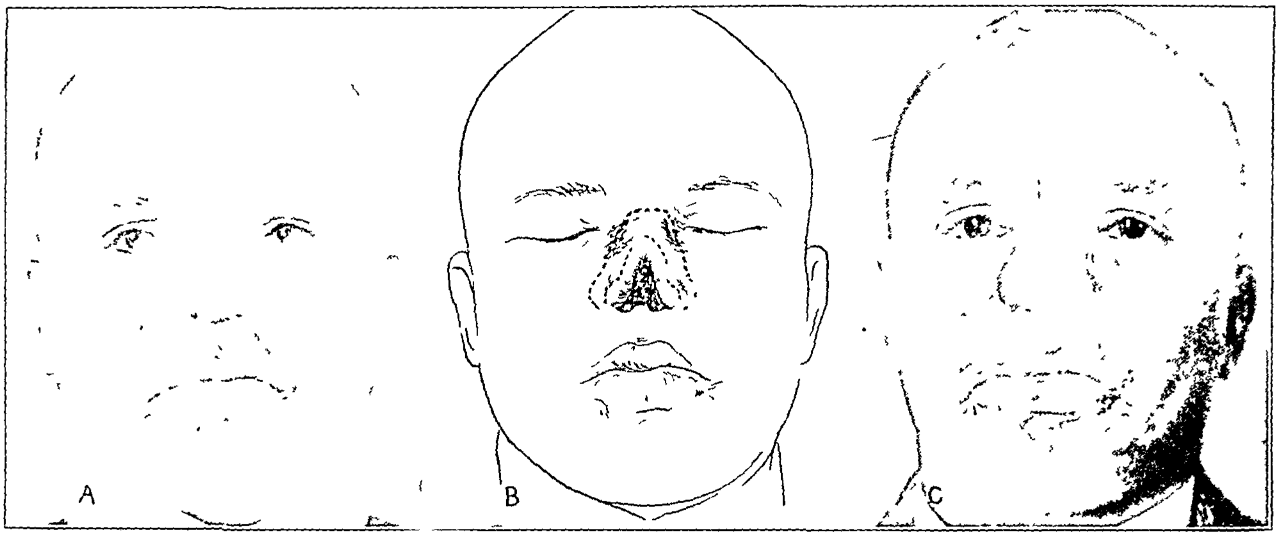

Fig 4—Loss of lining and much of covering; the remaining part had healed over leaving no external opening The first step was to make an airway by turning in the skin to line the anterior part of the nasal tube (*B*) At the same operation a flap was raised from the forehead that provided for covering, lining and columella, and it was at once sutured back in place (Delayed transfer of the flap was practiced in all these cases) To hurry on the work the step of making a preliminary deep incision around the attachment of the new nose was omitted, and we subsequently had considerable trouble with the lateral spreading of the foundation, which partly accounts for the asymmetry of the alae shown in *C*

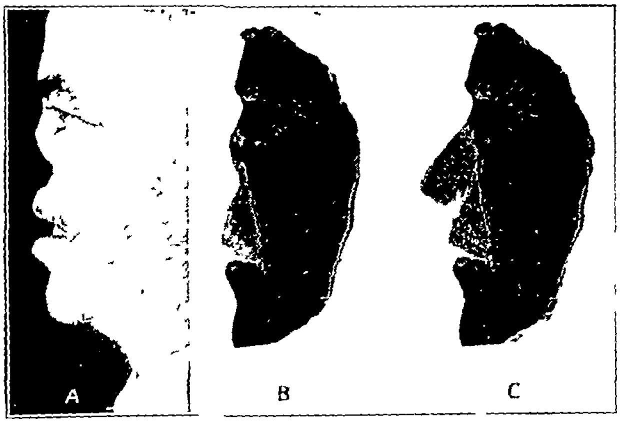

Fig 5—*A*, a man who has lost the lower half of the nose, adjacent part of the cheeks, and almost all of the upper lip except the mucosa *B*, the lip built up in clay from which a pattern was cut of a flap to be made from the right side of the forehead, base at the temple, this restored the lip and cheeks *C*, nose built in clay on the clay lip From the former, a pattern was cut for a flap from the left side of the fore head, pedicle over inner end of left brow, to make the lining, covering and columella of the nose By having the whole plan worked out in this way, the time of hospitalization is materially shortened and the number of operations is reduced

The next step is to locate available material for the repair. Cartilage is commonly the most available and docile supporting material. Cartilage or bone is most often used in the form of an insert in the dorsum (Figs. 6, 28 and 29). Cartilage can be incorporated into the lining or covering flap before transferring it, but this is not the best plan (Figs. 7 and 8). If bone is used, it must have contact with bone; otherwise it will be absorbed. In some instances an osteoplastic flap is very useful (Figs. 9, 10 and 11). It is neither practicable nor necessary to reproduce the septum, but a good columella is a necessity (Fig. 12). In certain cases, the depressed or misplaced framework of the nose can be chiseled from its unnatural attachment and held in the desired position by a dental splint until union has occurred (Fig 11).

A pedicle flap from the arm (Figs. 15, 16 and 17), neck or forehead is commonly used for nasal covering. The ideal source is the forehead when sufficiently broad; it molds well and closely resembles the normal nose skin, but its use leaves a permanent blemish that cannot be entirely hidden by the most perfect skin graft (Fig. 12). In the presence of an extensive defect, baldness is sometimes a blessing (Figs. 18 and 19). Our observation of depilation by irradiation is that it is uncertain of result (Figs. 15, 16 and 17). In women, a transverse flap from the upper part of the neck leaves comparatively little ultimate marring and

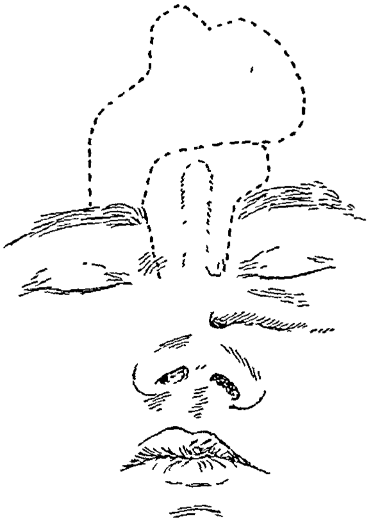

Fig 8 (same patient as in Figure 7)—The central flap included the full thickness to the periosteum, and between the muscle and skin a piece of the ninth rib cartilage was implanted at the time the flaps were first raised Later the center flap was dropped down raw surface out, to form the lining, and the lateral flap was rotated so that it had skin surface out to make the covering of the new nose may give grateful relief from a double chin, but the amount of material is limited (Fig. 20). A flap from the inner surface of the arm is of good surface texture but poor color, and may contain coarse fat lobules that prevent satisfactory contouring; the circulation of this flap is not always good (Fig. 21). A jump flap might be used. Except for small defects, the obtaining of flaps from the cheeks is usually not good practice (Figs. 22, 23 and 24).

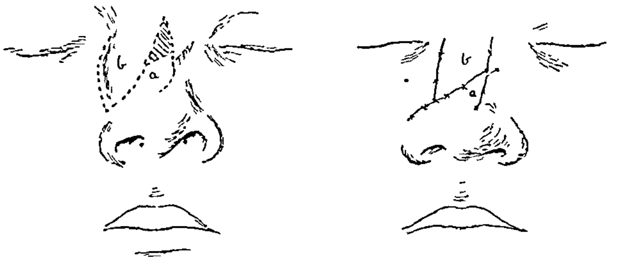

Fig. 11 (same patient as Figure 9).—To save the patient's limited time, flaps were made containing the full thickness of the nasal wall, skin, bone and cartilage, and mucosa, and these were readjusted in a way that brought the ridge to the midline and lengthened the nose. The septum was resected at the same operation. The long upper flap was held in place by a wire suture fastened to the upper left first molar. Patient returned home twenty-one days after operation.

The lining in some cases can be procured from the dorsum of the remaining part of the original nose (Figs. 3, 15, 16, 17 and 21), but in others will have to be provided from the same source as the covering. We have used a plan for restoring the whole nose by one flap which will furnish covering, lining, columella and alae, and in the folding, the general form of the nose will be reproduced.[1] The columella is frequently obtained from the lip. Except in a few instances, lining the new nose with free Thiersch or full thickness skin grafts has not been as satisfactory in our hands as has the use of a flap. In partial reconstruction, carefully made suture lines on the external surface of the nose, in time, usually become almost or quite invisible (Figs. 25 and 26). When destruction has been extensive, it may be necessary to build up the cheeks and lip before beginning on the nose itself, and this may make great inroads on the supply of desirable material (Figs. 27, 28 and 29). In planning the new nose, its final blood supply, after cutting the pedicle of the flap, must be considered. In some cases the covering flap may extend out on the cheek to insure adequate circulation. Wherever possible, ample provision should be made for shrinkage, failure of union with resuture, and adjustment of flaps; but, on the other hand, the more accurately the flaps are cut and sutured at the first operation, the fewer secondary adjustments will be required. This is a matter that furnishes opportunity to exercise nice judgment based on previous observations and catastrophes. A preoperative estimate of the patient's psychology is tremendously important. Some will be satisfied with any ordinary result, or less, while there are a few whose mental depressions will not be even partially relieved by the best obtainable result. Suicide or a life given over to useless self-pity has been the occasional sequence of really good nasal reconstructions (Figs. 30, 31 and 32).

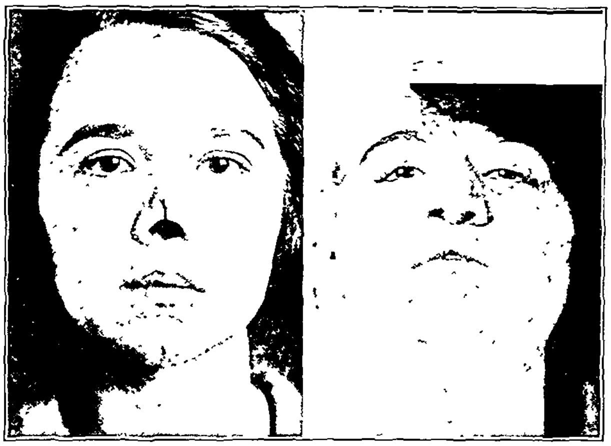

Fig. 12 (same patient as in Figure 3).—Columella made from an intermediate part of the forehead flap that lined the nose and made the tip. No attempt made to reproduce the septum. The hair is worn low on the forehead to hide a not very good full thickness skin graft.

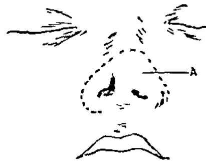

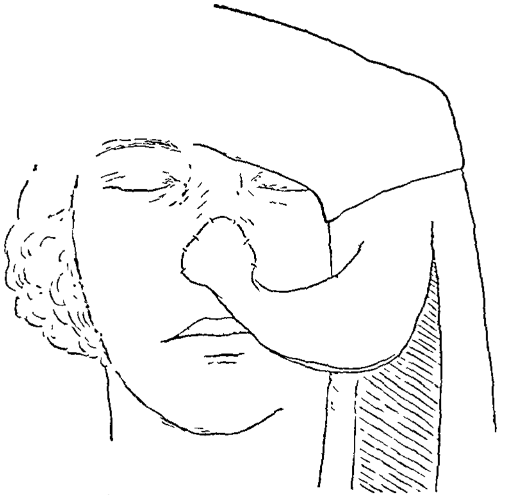

Fig. 17 (same patient as in Figure 15).—Repair was made by turning down the skin of the alae and the lower half of the dorsum to form lining, and covering this raw surface with a flap from the arm. The covering flap was conformed with sutures to reproduce the natural curves of the alae and tip. There was quite a bit of hair on the arm flap, the destruction of which required sufficient radium irradiation to cause a severe surface blistering. Such a reaction must for a time cause some apprehension as to the effect on the flap itself. *A*, loosened and turned down for lining.

The conclusions from army and civilian observations are that few people are content to wear permanently an artificial feature, no matter how good (Figs. 33 and 34).

The more carefully and accurately a plan is worked out before actual surgical work is begun, and the more closely good surgical principles are adhered to, the better will be the result, the shorter will be the time required, and the fewer will be the necessary operations.

Metropolitan Building.

ABSTRACT OF DISCUSSION

Dr. George M. Dorrance, Philadelphia: Dr. Blair is to be congratulated on his excellent results. There are certain facts on which we differ; one is taking the flap from the arm or chest. One must be very careful not to make these persons conspicuous. If one takes a flap from an arm or chest, it usually has a blanched white color, which is very different from the face. I have a patient under my care at present who was operated on fourteen years ago by a surgeon who replaced a cheek and nasal bone defect with a flap from the chest. Her appearance now is quite grotesque, on account of the white color of the flap. Flaps from a chest and arm have a tendency to take on fat in most cases.

---

[1] This plan was presented, with the writer's consent, by Dr. Robert Ivy before the Section on Stomatology of the American Medical Association in June, 1924 (Ivy, R. H.: Repair of Acquired Defects of the Face, J. A. M. A. 84: 181 [Jan. 17] 1925).

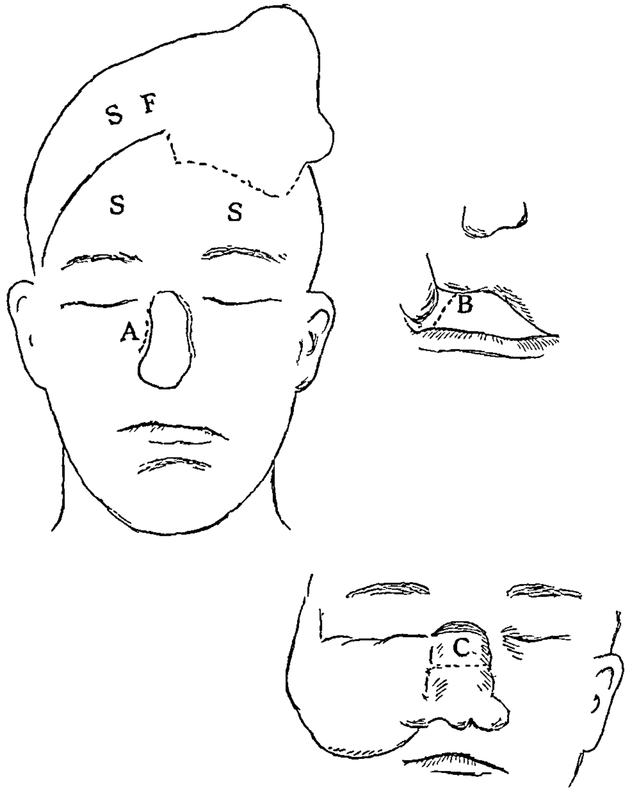

Fig. 19 (same patient as Figure 18).—Repair was made from a large flap cut from the bald vertex scalp with a left temporal base This was so planned as to furnish lining, covering and columella, and had a prolongation out on the right cheek to insure a blood supply after the pedicle was cut. The lip had been partially restored by cheek flaps, but was later supplemented by a piece taken from the pedicle of this vertex flap. Before any of this was done, the cheeks were "stepped" forward to furnish a foundation for the new nose (Figs. 28 and 29). *S, S,* scar; *S F,* scalp flap; *A,* cut and sutured for fixation; *B,* brought forward and sutured to push lip forward; *C,* turned in for lining.

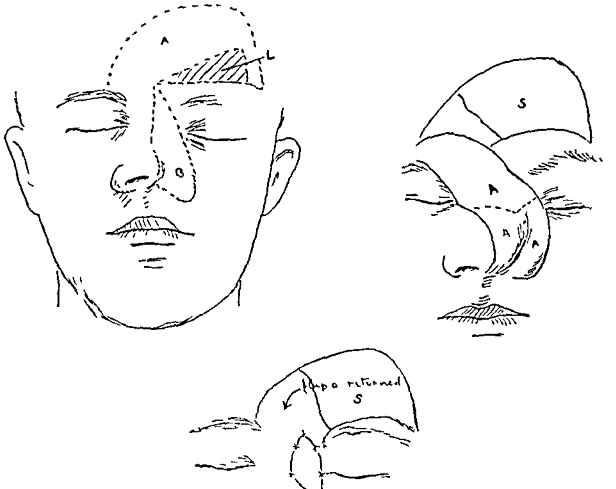

Fig. 24.—Plan of making flaps used for patient in Figures 22 and 23: *b,* lining of nostril; *S,* skin graft.

Dr. George C. Schaeffer, Columbus, Ohio: I wish to emphasize three points. The first is the necessity of a good lining for the flap. A forehead flap will contract, unless there is a good lining. It can be lined by scar tissue or by a layer of epithelium or this modeling compound, placed under the skin covered by the Thiersch graft. Cases lined in this way are very dry, and patients complain of considerable dryness of the nose. In several recent cases, I have tried the transplantation of small strips of buccal mucosa from the mouth, putting these on the flap before putting the flap into shape. My experience has not been enough to warrant me in saying what the results are going to be, but I believe the method has a future. The second point is the necessity of a good appliance to hold the tissues in shape while healing is taking place. It is much easier to build a nose over an appliance and hold the nose in good shape than to put in an appliance to hold the nose in shape after it has become distorted. The third point is the advisability of using cartilage for a framework rather than other tissues. Recently it has come to my notice that some men are using ivory, shaping it so as to make a bridge for the nose. I speak of this practice merely to condemn it, because I think ivory is nothing more or less than a foreign body, which will later give trouble. As to the transplanting of the cartilage before the transplanting of the flap, I understand that Dr. Blair favors the method of transplanting the cartilage after the flap is in place. It is the method of choice, but so far my experience has been that transplanting cartilage under the flap is very satisfactory.

Dr. Robert H. Ivy, Philadelphia: Dr. Blair has demonstrated that it is possible to reconstruct a presentable, prominent and functioning external nose from a single forehead flap, and my own experience tends to confirm his findings in every respect. To obtain good results, the flap must be cut from a pattern previously prepared from a wax or clay model of the nose, built on a plaster cast of the face. The folding of the distal end of the forehead skin flap in the manner advocated by Dr. Blair is sufficient to provide lining for the lower part of the nose and to make the columella. By this means alone, sufficient prominence and rigidity of the tip of the nose can usually be obtained, without the use of cartilage or other supporting tissue in this region. Costal cartilage implantation is occasionally of advantage, to give greater prominence and stability to the upper part of the nose where the nasal bones are absent or depressed. But even then the forehead flap alone usually gives sufficient prominence. When costal cartilage is used, it can be implanted, first, under the forehead skin before bringing down the flap; secondly, under the remaining nasal skin, later bringing down the flap over it, and thirdly, under the forehead flap after it has been brought down. I believe with Dr. Blair that one of the last two plans is far preferable to the first, because it is much more difficult accurately to shape and place the cartilage beneath the skin of the forehead before bringing the flap down than it is to insert the cartilage at the beginning in its final position. I have found that the defect on the forehad can be best covered by a full thickness skin graft from the abdomen and supported by a sea sponge dressing under pressure.

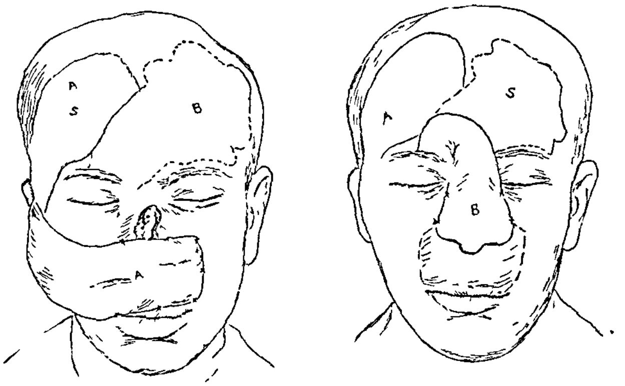

Fig 29 (same patient as in Figure 28).—The first step was to restore the lip with a flap from the right side of the forehead. The nose flap, furnishing lining, covering and columella, came from the left side (*A* and *B*); *S,* skin graft.

Dr. W. W. Carter, New York: I began transplanting bone about fifteen years ago. I believe the clinical results now enable me to speak with some certainty as to what the final results are in this work. Bone and cartilage have distinctive uses. I use bone where I need strength and growth in transplanted tissues, I use cartilage chiefly as a filler, and I use combined bone and cartilage for the purpose of reproducing a natural nose and preserving the resilience of the nasal tip. Bone not only lives but it grows, and its growth is regulated by the functional demands of the part. My clinical experience assures me that bone can be successfully transplanted in the young. I have had two or three patients brought to me in whom it was absolutely necessary to transplant the bone because the parents demanded it. The deformity in one child was preventing her from going to school, and it was necessary to do the operation. Some of these cases are of sufficiently long standing for me to note final results and express an opinion. In one case in particular, the patient was operated on at 10 years of age. Now, at 13½, this young girl has a perfectly developed nose. Apparently the nose has the growth and vigor normal for her age. Bone, when properly transplanted, is not absorbed, but when it is not properly transplanted it is absorbed. If infection occurs there is going to be some loss of bony tissue even though the infection is quickly eradicated. The loss may be molecular, giving the edge of the transplant a dendritic appearance under the roentgen ray. Bone is pretty nearly as resistant to infection as cartilage. It continues to grow, and the growth is regulated by the functional demands of the part. I have noted in several cases in which fracture of the transplant has occurred that the ends of the fragments reunited in a perfectly normal manner. In one case, two years after the operation the transplant was fractured; it was set and the fragments became reunited.

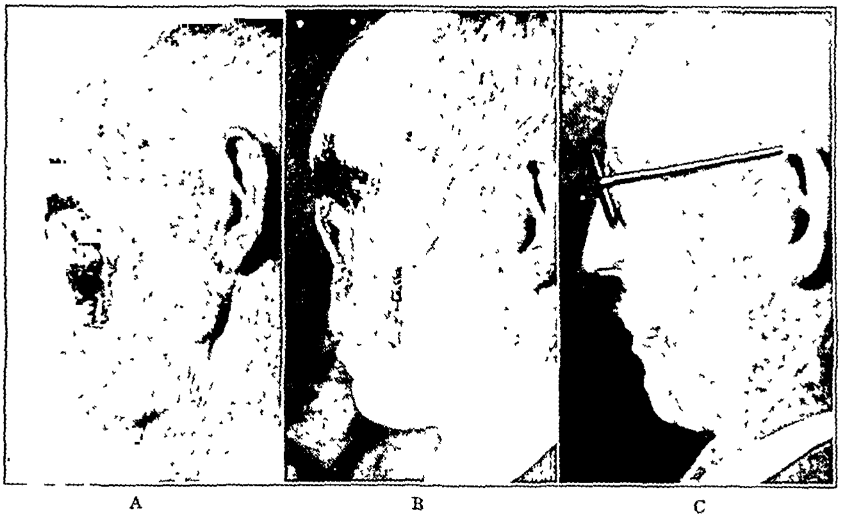

Fig. 34.—Man who had lost the nose, the whole upper lip, the contents of the orbit with the lids, and much of the cheek from recurrent carcinoma. The forehead was not available as a source of flaps The upper lip was made and the orbit and cheek defect covered with a transverse flap from the neck (*B*). The nose is of painted vulcanite resting on a spur on a dental bridge and held by spectacles (*C*).

Dr. V P. Blair, St. Louis: Ivory is to be classed with other foreign substances. There is a great deal of talk at present about the use of ivory. It comes out of Germany, and I think its use will go the way of other attempts to implant foreign substance in the tissues. I have had the opportunity of seeing a number of roentgen-ray studies of Dr. Carter's bone transplants, and I agree with him. I have a few children scattered over the country on whom I have done the bone-cartilage transplants described, hoping they would grow. He greatly encourages me, because I have not seen them since.

Infant Mortality.—According to the U. S. Children's Bureau, New Zealand has just broken her own low world record for infant mortality; only forty infants for every 1,000 born now die in their first year of life. The record for the United States is seventy-two for every 1,000.—*Science Service.*

ADIPOSIS DOLOROSA (DERCUM'S DISEASE)

A CLINICOPATHOLOGIC STUDY *

N. W. WINKELMAN, M.D.
PHILADELPHIA
AND
JOHN L. ECKEL, M.D.
BUFFALO

In 1892, Dercum[1] first gave the name "adiposis dolorosa" to a new clinical entity present in three cases, two of which had come to necropsy. Since that time about 200 reports have been added to the literature. Of these we have been able to find only fifteen that have come to necropsy, and there has been such a great diversity of findings that any additional information gained from necropsy material should be reported. For this reason the following case is presented.

REPORT OF CASE

History.—E. B., a colored widow, aged 50, was admitted to the Philadelphia General Hospital, June 21, 1924, because of a cough, which had been present for one week As this patient presented extreme obesity, this phase of her case was studied. There had been no cases of obesity in her family so far as she knew. She began to accumulate fat rather gradually in girlhood, but there had been no change in the last twenty years. The obesity was most marked about the thorax, abdomen, back, hips and upper arms. At no time were her hands, face or feet involved. For "years" her fat had been painful on pressure. She had been married, but her husband had died many years before of unknown cause. She was never pregnant. She was up and about the house until one week before admission to the hospital. At this time she developed a cough. There had been ulcers on the legs.

Examination.—The patient was huge, weighing 460 pounds (208 kg). The abdomen was very large, and the fat hung down to the knees when she stood upright. About both legs there were numerous ulcers, which were discharging freely and had an offensive odor. She had bullae on the thumbs. The arms, thorax, back and hips were very large. The upper arm measured 23 inches (58 cm.) in circumference, the wrists 8 inches (20 cm.); thighs, 34 inches (86 cm.); ankles, 12 inches (30 cm.), and the abdomen 72 inches (182 cm.). The breasts were large and pendulous. There were large rolls of fat about the back, thighs and abdomen, with deep creases and ulcers between the folds. The face, hands and feet were free from excessive fat. The fat was nodular and painful on pressure. There was slight dyspnea. She fatigued very easily, both mentally and physically. Her temperature during her few days in the hospital ranged from 98 to 102 F.; the pulse rate ranged from 80 to 108 per minute, and respirations varied from 20 to 30 per minute.

The heart was normal in size, and the sounds were of fair quality; there were no murmurs; the vessels were moderately sclerotic.

---

* From the neurologic laboratory and wards of the Philadelphia General Hospital.

* Read before the Section on Nervous and Mental Diseases at the Seventy Sixth Annual Session of the American Medical Association, Atlantic City, N J., May, 1925.

[1] Dercum, F. X.: Three Cases of a Hitherto Unclassified Affection Resulting in Its Grosser Aspects, Obesity, but Associated with Special Nervous Symptoms, Am J. M Sc. **104**: 521, 1892.

The ulcers on the legs varied in size, depth and width. About the largest there were elevations, except in the upper portion of the thighs, where some were very red and were discharging freely. There was a papulovesicular eruption of acute appearance on the upper thighs. No visual disturbances could be made out, and there was no history of convulsions or of hemorrhage. Through some error, no laboratory work was done before her sudden death, which occurred on the fourth day after admission.

Necropsy (Dr. Case).—The body was that of an extremely obese adult negress (Fig. 1). The subcutaneous fat in the anterior abdominal wall measured 16 cm. in thickness. The mesentery and omentum contained a relatively small amount of fat. The heart was uniformly enlarged (490 gm.), with but slight increase of fat at the base. The myocardium was firm, red and of good texture, without fatty infiltration; the valves were competent. The left suprarenal measured 7.7 by 3.8 by 2.4 cm. The increase in size was due to an adenomatous growth of cortical tissue forming a large circumscribed, flattened, yellowish mass, occupying most of the organ. The right suprarenal was within normal limits as to size and structure. The kidneys were large and firm; the capsules stripped easily, and the structure within was normal. The uterus was firm and contained several polyps, some of which were necrotic. The ovaries were small and atrophic. The pancreas was firm and of a light straw color, with little or no fatty infiltration. The liver weighed 2,860 gm. It was firm and brownish red. There was no gross evidence of fatty change, a point of interest in view of the extreme obesity. The thyroid was not enlarged; it was firm and dark red. The cut surface was dark red and had a translucent appearance. The aorta showed moderate sclerosis. The sella turcica was enlarged in all directions; it measured 2.2 cm. laterally by 2 cm. anteroposteriorly by 1.4 cm. in depth. The pituitary body was distinctly enlarged, measuring 2.1 by 1.8 by 1 cm. The infundibulum and tuber cinereum were grossly normal. Lying on the surface of the sella was a dark red, soft, hematoma-like mass. On sagittal section this extended one-half the depth of the organ, and then became yellowish and slightly laminated. On the right this was replaced by a cavity which was small and with an irregular outline.

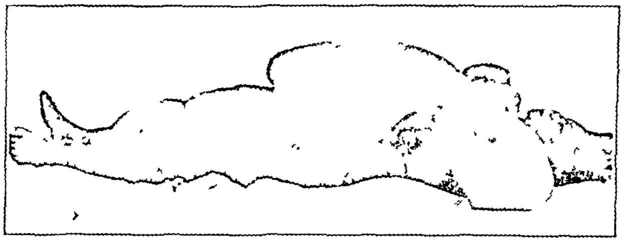

Fig. 1.—Postmortem appearance of patient.

Microscopically (Dr. E. B. Krumbhaar), the pituitary (Figs. 2 and 3) was made up chiefly of cellular tissue resembling the anterior lobe, and in the center was an open space with irregular walls of fibrous tissue (necrosis). At each end, tissue resembling posterior lobe was seen, but this contained more cells and congested vessels than normal. The normal relations of the various lobes could not be made out. The cellular structure varied in different parts; it was unusually congested throughout. In some places the alveoli resembled the normal anterior lobe. No accurate differentiation into acidophil, basophil or chief cells was possible. In other places the alveoli arrangement was lost, and the cells were packed together without arrangement and without connective tissue stroma. The cells contained round or oval vesicular nuclei, with a small amount of acid-staining protoplasm. In one place in the capsule was a small nodule that contained relatively undifferentiated cells packed close together.

Microscopic sections of other organs (Dr. Belk) showed as follows: There was slight fatty infiltration of the pancreas. The left suprarenal showed adenoma (Fig. 4). The ovaries were atrophic and contained small cysts. The liver showed cloudy swelling, with moderate fatty infiltration and portal cirrhosis. There were benign papillomas in the uterus. The thyroid was normal.

Serial sections of the region of the tuber cinereum showed fairly recent petechial hemorrhages in the region of the walls of the third ventricle (Figs. 5 and 6). No other abnormality could be made out. The rest of the brain showed nothing of note.

LITERATURE

The following is a brief abstract of the cases coming to necropsy:

Case 1 (Dercum,[1] 1892).—F., aged 64, married, the duration of whose obesity was fifteen years, weighed 300 pounds (136 kg.). The fat had accumulated gradually, and it was tender on pressure. She had occasional uterine hemorrhages. Postmortem examination revealed the thyroid small, indurated and infiltrated by calcareous matter in both lobes. The liver showed fatty infiltration. There was an ovarian cyst. No mention was made of the pituitary gland. No microscopic examination was done.

Case 2 (Dercum,[1] 1892).—F., aged 60, began to accumulate fat in her eighteenth year. She had a history of epistaxis and hematomas. The fat was tender, and there was mental torpor. Necropsy showed the fat distributed in irregular masses. The thyroid was larger than normal, was firm and contained much calcareous matter. The liver showed fatty infiltration. The kidneys were shrunken. No mention was made of the pituitary gland. No microscopic examination was done, as the specimens were lost.

Case 3 (Dercum,[2] 1900).—A widow, aged 51, whose condition began in the arms and spread to the trunk, had had painful swellings and neuritic pains. Necropsy showed an irregular, atrophied thyroid gland, with occasional areas of attempts at compensatory hypertrophy. There was extensive interstitial neuritis of the nerves in the fat masses. The tract of Goll showed slight degeneration.

Case 4 (Burr,[3] 1901).—A very obese woman, aged 36, who weighed about 300 pounds (136 kg.), died of nephritis. The fat was painful. Necropsy revealed a glioma of the pituitary gland, which was the size of a walnut. Marked internal hydrocephalus was present. The ovaries were small and hard. The peripheral nerves in the fat showed interstitial changes. The thyroid contained a concretion the size of a small chestnut, also colloid degeneration and atrophy with absence of secreting cells in many acini. The liver showed fatty degeneration.

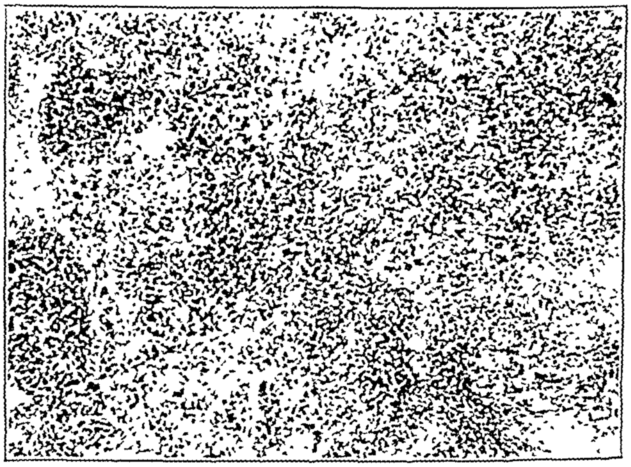

Fig. 2.—Marked adenomatous changes in pituitary as seen under low power.

[3] Burr, C. W.: A Case of Adiposis Dolorosa with Necropsy, J. Nerv. & Ment. Dis. 27: 519, 1900.

Case 5 (Dercum and McCarthy,[4] 1902).—A man, aged 39, whose obesity began at 17, had had convulsive seizures during his last five years. There were frequent attacks of epistaxis. Necropsy revealed adenocarcinoma of the pituitary body. There were fibroid hemolymphoid nodules in the subcutaneous fat. There was interstitial neuritis of the nerve filaments in the fat nodules. The spleen revealed interstitial hyperplasia. The testes were defective. The right suprarenal was hypertrophied.

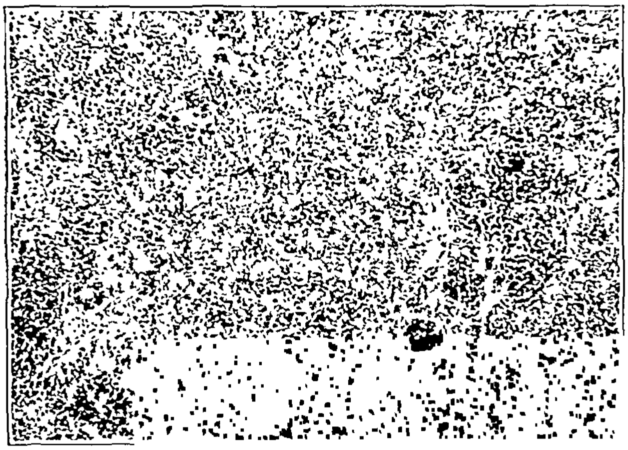

Fig. 3.—Marked adenomatous changes in pituitary as seen under low power.

Case 6 (Ballet,[5] 1903).—Obesity was present for eight years in a woman, aged 68. She was very depressed and suicidal. Necropsy revealed diffuse sclerosis of the thyroid gland and interstitial neuritis of the nerve filaments in the fat nodules. There was fatty infiltration of the liver. No examination of the pituitary body was made. The cord and cortex were normal.

Case 7 (Rome,[6] 1904).—A woman, aged 55, with obesity for ten years, had had no vasomotor nor sensory disturbance. Necropsy revealed no abnormality of the thyroid, pituitary body, or cord. The heart was dilated. There was interstitial nephritis. There were no microscopic lesions to explain the condition.

Case 8 (Guillain and Alquier,[7] 1906).—F., aged 57, whose condition had existed ten years, had had mental symptoms and right hemiplegia. Necropsy revealed the pituitary body double the normal size, with marked increase of connective tissue in the anterior lobe and changes suggestive of alveolar carcinoma. The thyroid was hypertrophied with an increase of connective tissue stroma. The follicles were large and filled with colloid. No examination of the pancreas or the suprarenals was reported.

Case 9 (Loening and Fuss,[8] 1906).—A woman, aged 66, who began to accumulate fat at the age of 12, weighed 185 pounds (84 kg.). The fat was tender. She died of erysipelas. Necropsy revealed a thyroid the size of a walnut, with increase of the connective tissue stroma. The ovaries were atrophic.

Case 10 (Price,[9] Case 1, 1909).—A woman, aged 57, who lived but eleven days after admission, had no available history. A postmortem examination revealed marked increase of interstitial connective tissue of the thyroid gland with inflammatory changes. One lobe showed marked infiltration, while the other showed compensatory hypertrophy. There were some inflammatory changes in the pituitary body, with areas of round cell infiltration, suggestive of an alveolar carcinoma. There was interstitial neuritis in the fat. The ovaries were sclerotic.

Case 11 (Price,[9] Case 2, 1909).—In this woman, aged 48, no history could be obtained. Her weight was 308 pounds (140 kg.). A postmortem examination revealed marked increase of connective tissue of the thyroid, and a dilatation of the acini with infoldings of the cuboidal epithelial lining. The pituitary body showed several areas of round cell infiltration.

Case 12 (Marchand and Nauet,[10] 1911).—F., aged 58, the duration of whose obesity was nine years, proved at necropsy to have a thickened pia, with narrow cortex and increase of neuroglia. There was inflammation of the peripheral nerves in the fat. The thyroid was large, with increase in the connective tissue. The follicles were normal. In places there was typical adenomatous structure with much colloid in the follicles. No mention was made of the pituitary body or the pancreas. There was atrophy of the ovaries with disappearance of follicles.

Case 13 (Falta,[11] 1913).—Necropsy done on a man, aged 56, in whom the duration of obesity was twenty years, revealed the thyroid as having a colloid struma, but everywhere abundant gland tissue of normal consistency was still found. There was perivascular infiltration in the fat tissue. No definite pathologic changes in the gland were present.

Case 14 (Dammann,[12] 1913).—The condition of F., aged 61, had existed twenty-six years. At necropsy the thyroid was not enlarged, but the left lobe contained colloid areas with dilated follicles. The connective tissue was thick and gave the appearance of an adenomatous hypertrophy. The pituitary body showed slight infiltration about Rathke's pouch. The pancreas showed focal fat increase. The suprarenals had hyaline areas. The ovaries were atrophic and had no remaining follicles.

Case 15 (Brüning and Walter,[13] 1919).—A boy, aged 10, in whom the condition had existed but nine months, had polydypsia, polyuria, glycemia and convulsions. There was amaurosis and augmented development of the secondary sex characteristics. Necropsy revealed an alveolar adenoma of the pituitary gland.

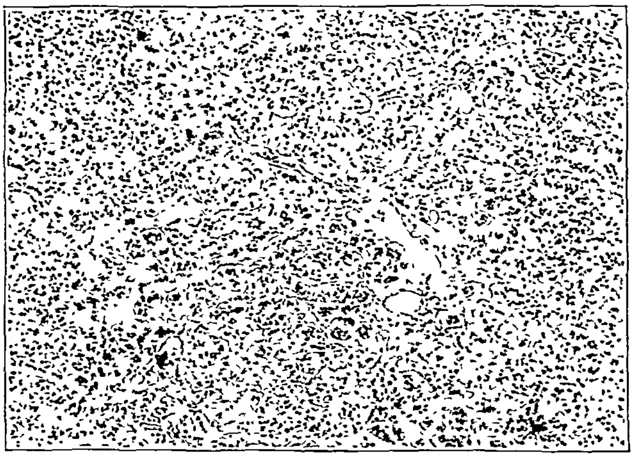

Fig. 4.—Adenomatous arrangement of suprarenal as seen under low power.

COMMENT

The case herein described fits in with the generally recognized syndrome of Dercum's disease, showing the following features: (1) obesity (exclusive of face, hands and feet), weight 460 pounds (208 kg.), with painful masses; (2) ulcers on the legs and bullae on the fingers, and (3) asthenia.

The pathologic findings were an adenoma of the anterior lobe of the pituitary body with enlargement of the sella turcica, an adematous hyperplasia of the left suprarenal gland, atrophy of the ovaries, and many recent hemorrhages in the thalamus and subthalamic regions.

On reviewing the necropsy findings of the fifteen cases in the literature, one is impressed by the pluriglandular involvement in most of the cases. In only two cases were there no definite changes in the ductless glands (Rome and Falta). Of the eleven patients in whom the pituitary body was examined, eight showed definite alterations; the thyroid was abnormal in twelve cases; the sex glands were pathologic in nine; the suprarenal in three, and the pancreas in two.

Our own case showed pituitary, suprarenal and ovarian pathologic changes. It is of interest from a clinical standpoint to note that the condition is five times more prevalent in the female and that most cases develop after the age of 35.

In view of the recent work on the tuber cinereum (Bailey and Bremer,[14] Camus and Roussy[15]), serial section study of this region was done. Nothing was found that could throw light on the etiology of the disease. The occurrence of fairly recent hemorrhages in the vicinity of the tuber cinereum and in the pituitary body may be evidence of the hemorrhagic tendency so frequent in this disease.

Dercum originally attributed the condition to a dysthyroidia which caused a reduction of fat combustion and inflammatory changes of the nerves. Since then other theories have also been advanced; viz., that it is a chronic intoxication of endogenous origin. Others believe the pituitary body at fault, while still others are of the opinion that it is a pluriglandular affection. Strübing[16] and Thimm[17] theorized on a trophoneurosis.

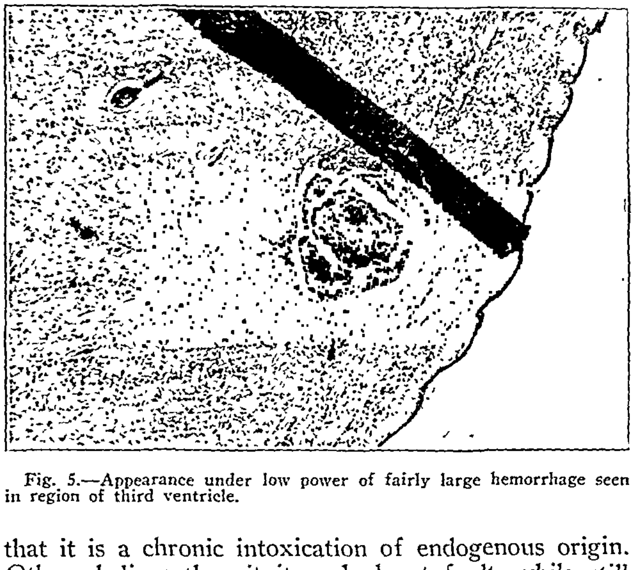

Fig. 5.—Appearance under low power of fairly large hemorrhage seen in region of third ventricle.

The relation of the other forms of obesity to Dercum's disease has been dwelt on by several, including Lyon[18] McCarthy and Karsner.[19]

Falta[11] believes that the changes in the ductless glands are accidental or coincidental. From a study of one case, no definite deductions can be made, but with three of the glands of internal secretion diseased, and knowing that there is an interrelationship between all the ductless glands, we feel that the pluriglandular hypothesis is best suited to explain the syndrome.

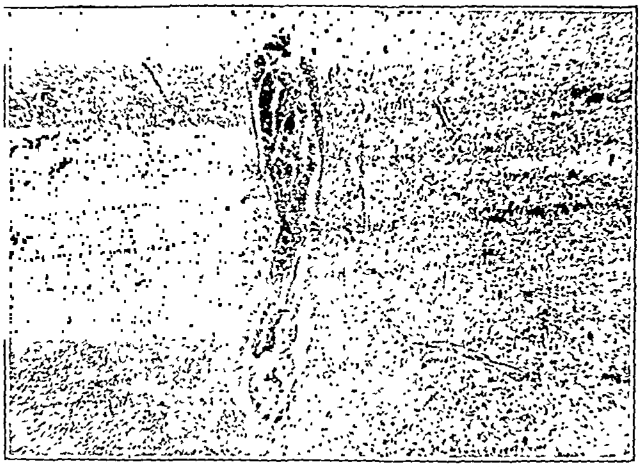

Fig. 6.—Appearance under low power of fairly large hemorrhage seen in region of third ventricle.

SUMMARY

1. The case of adiposis dolorosa that we report was quite typical clinically.
2. Pathologically, there was enlargement of the sella turcica with an adenomatous growth in the pituitary, recent petechial hemorrhages in the region of the third ventricle, and adenoma of the left suprarenal, and atrophic ovaries.
3. The theory of endocrine malfunction seems best suited to explain the symptoms in this case.

319 South Eighteenth Street—589 Delaware Avenue.

ABSTRACT OF DISCUSSION

Dr. Walter Timme, New York: We have seen in our clinic at the Neurological Institute a few cases of Dercum's disease in the last six or seven years, none of which have, so far as we know, come to necropsy. Yet the cases that we see fall so definitely into a type of a well marked pleuriglandular syndrome that we have come to look on them as belonging to this group. Practically all our cases show on roentgen-ray examination a large thymus, and the history of the cases shows an original thymus or hypoplastic state dating from puberty, even antedating puberty. Because they are not only extremely fatigable and backward, not necessarily from a mental but from a biochemical point of view, the picture can hardly be mistaken. They show a small blood vessel system and a small cardiovascular system. The fundus of the eye shows very small vessels; the blood pressure is usually low. There is an enlargement of the spleen but hypoplasia of other organs. This is of extreme importance in diagnosis, especially the notably small suprarenal, thyroid and the pituitary glands. In the course of a probable compensatory process, which brings these cases after a while toward normality (even if they don't reach it), these hypoplastic structures tend to become hyperplastic or overactive, with occasional formation of adenomas. Several patients belonging to this group (not merely Dercum's disease) have been operated on for pituitary and thyroid adenomas. Many of them in the course of their progress give histories of hemorrhages, occasionally into the central nervous system, and show definite signs of such lesions. Occasionally, after lethal termination, hemorrhages are found in the suprarenals and in the ventricles of the brain, the arteries of the ventricles, particularly, being subject to such hemorrhagic insults. Those hemorrhages are due partly to a hypoplasia of the arterial walls, readily permitting such results. Occasionally these hemorrhages give no manifestations. It sometimes happens that the pituitary is involved and enlarges; these cases give pituitary disturbance later in life. Occasionally, it is the thyroid that gives symptoms as the cases progress, or the suprarenals may bring on disturbances. Hence, there is no unanimity as regards the pathology of a finished case, because of the fact that any one or all three of these organs are engaged in the compensatory process. In the case presented by Dr. Eckel, we have the hemorrhages, the adenomas, the pituitary involvement and the suprarenal involvement. But they all began from an original hypoplastic condition, the emergence from which is shown by the manifestations of the particular gland at fault.

Dr. **Theodore Diller**, Pittsburgh: In 1886 and 1887, I was a resident physician at Blockley Hospital, and at that time, serving under Dr. Dercum, I saw the first case that he described, which has become a classic in literature. I remember the patient distinctly, and I wish to pay a tribute to Dr. Dercum for his skill in describing this case I remember well the weblike appearance that the patient presented when she held out her arms; it was a case with no name until Dercum came along. This disease is an illustration of many rare ones that occur in neurology; having seen one, a person could not fail to recognize another if he saw it. It so happens that in my experience of nearly forty years in neurology, I have seen only one other case and that was about twenty years ago. I see this woman from time to time. She has not such a marked case, but it seems about stationary. She is neurasthenic, has fatigability, and all the symptoms that Dr. Timme has been speaking about.

Dr. **J. D. McCarthy**, Philadelphia: No mention was made in the record of the pathology and description of this case of the underlying diagnostic factor in this group of cases. In the Dercum group of cases, as differentiated from the other pathologic fat conditions, one finds, if he studies the fat under microscopic slides, evidence of a peripheral neuritis of the nerve filaments, going into tumors in the fat tissues. The fatty masses are encapsulated and there is also a condition of increased vascularity. I was surprised to hear Dr. Timme say that he has seen so many of these cases, because in the Philadelphia General Hospital in the last thirty years there probably have not been more than three or four of these cases, with the tremendous amount of material that we have, that have come to necropsy. We have, however, a large number of conditions of pathologic fat, which we do not consider as adiposis dolorosa. Many of these cases look very much like the case that was shown here, with tremendous masses of fat in the abdomen: more particularly when the patients get to the point at which they are bedridden, there is what one might term an increase in vascularization, and the fat tissue of the abdomen becomes infiltrated and tender. But that is not what Dercum or what I would consider a case of adiposis dolorosa. A case of adiposis dolorosa would be one in which there was pain at times, tendency of the fat to swell in localized areas at times, and these areas extremely tender to touch during the periods of congestion, at other times ordinarily tender, and associated with the endocrine changes that Dr. Timme and that Dr. Winkelman have found in this case. I think that the case I reported, with Dr. Burr, was one of the first cases in this group in which an endocrine association was reported, and that antedated Froelich's association of the gonads with pituitary disturbance. In that paper, the association of the ovarian function with the pituitary function and with secondary thyroid condition was very definitely pointed out. This was the first suggestion of the sexual influence of the pituitary, and the relation of the pituitary to sex development. That, I think, was possibly the second or the third case reported, and I believe it was the second necropsy. In the first necropsy by Dr. Dercum, as I remember, the pituitary, the thyroid or endocrine systems were not studied, but in our first case we found definite lesions of the endocrine system; in the cases reported by Dr. Burr and myself, the lesions were just exactly like the lesions reported in this case, adenomas of the pituitary and sclerosis of the thyroid, associated with ovarian disease. I do not see definitely how one can link these cases up, without pathologic findings, with a thymus condition. I think these cases show manifestation of disturbed metabolism due, as Dr. Timme has pointed out, not only to lesion of the pituitary but to a pleuriglandular condition, in which the pituitary might have been the primary lesion, but in which these other glands became secondarily involved. Any other assumption must be pure theory.

Dr. **J. L. Eckel**, Buffalo: There is just one question I wish to answer in closing, and that is regarding the pathologic examination of the nodular fat. The necropsy physician did not remove any of the fat for our analysis, and we had no opportunity to get it.

URINARY CALCULI

CHEMICAL COMPOSITION AND STRUCTURE IN RELATION TO RADIOGRAPHY *

DANIEL E. SHEA, M.D.
HARTFORD, CONN.

Since the advent of radiology, urology has made a remarkable advance toward more accurate diagnosis. In the earliest days of radiology it was considered quite sufficient if the shadow of a stone could be demonstrated; but during the last few years, through accumulated experience, more perfect technic and the introduction of pyelography, the roentgen ray has become a necessary adjunct to the study of urologic conditions. It is an accepted fact that there is a certain percentage of urinary calculi that fail to cast shadows on a roentgen-ray plate. For years a positive roentgenogram has been of value, but we still encounter

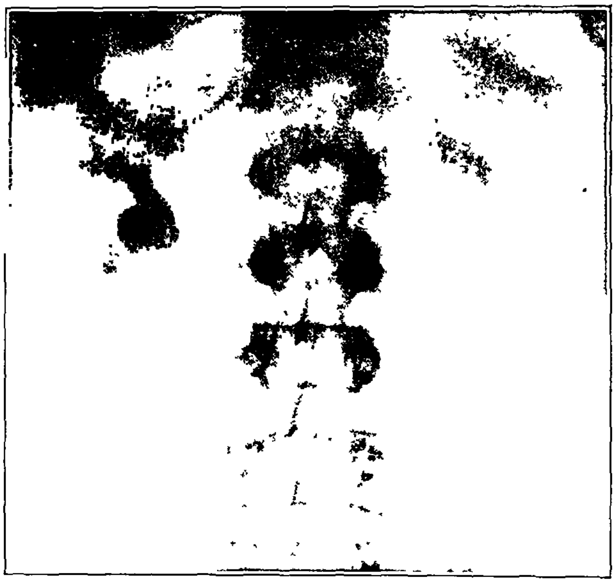

Fig 1.—Several calculi of same constituents: Density of shadow in stones within may be noted, neosilvol solution, calculi were positive to ordinary roentgen ray

cases in which a negative result does not always mean absence of urinary calculi. Too often, indeed, has it occurred, after the removal of urinary calculi which had previously been demonstrated by the roentgen ray, that the patient has had a ureteral colic before leaving the hospital and very often has passed another stone. Recent medical literature is rich with contributions on the so-called "recurrent urinary calculi," many of which were undoubtedly present but not discovered at a previous operation.

---

* Read before the Section on Urology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925

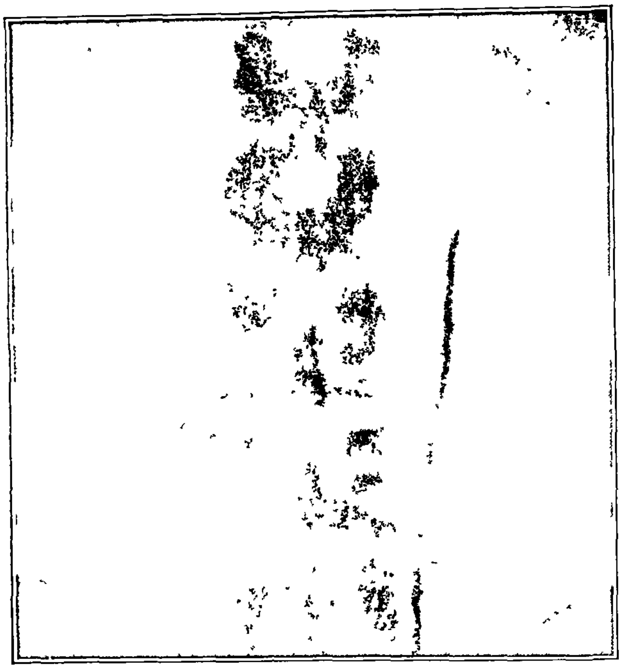

Fig. 2 —Two calculi in same kidney Good density of shadow in larger stone as a result of a large amount of calcium, small calculus is uric acid with some calcium.

Frequently, during the course of a urologic examination, the ureteral catheter meets an obstruction, and with negative roentgen-ray findings, ureteral stricture is considered proved by many, instead of merely suggested, and no further search is instituted for urinary calculi.

Finally, there are still those physicians in practice who rely on the roentgen ray entirely for the diagnosis of urinary calculi, notwithstanding the fact that there are few cities that do not have at least one physician who is trained in the use of the cystoscope, or if not, that such a physician is located within the radius of a very few miles.

Many investigators have written on the chemical composition of urinary calculi, and in nearly all the earlier works the authors considered uric acid and urates as the most important constituents of urinary stones. A review of the literature points out the fact that various authors differ as to the percentage of calculi containing these constituents. Thompson-Walker notes that out of 649 urinary calculi in the Hunterian Museum which were examined by Beneki, 74 per cent. contained uric acid or urates. Dickinson, during the examination of ninety-one renal stones, found uric acid or urates present in 70 per cent. Further examination showed that 63 per cent. of them contained calcium oxalate. On the other hand, Kuster found uric acid and urates to be present in only 3 per cent. of a series of 511 renal stones. In this same series phosphate was present in 31 per cent., while oxalate was found in 22 per cent.; xanthin was present in 3 per cent. of this series. Ultzman, in a series of 545 stones examined, found uric acid in 81 per cent., calcium oxalate in 5.6 per cent., and phosphate in 1.4 per cent. Bence-Jones asserts that 75 per cent. of all renal calculi are uric acid. Rosenbloom and Kahn report that in one series of twenty-six stones the majority were composed of calcium oxalate; and later, the same authors report a second series of twenty-six stones, all of which contained oxalates, 66 per cent. of them containing over 60 per cent. of oxalate. Moore has examined twenty-one stones from kidney and ureter and found that 70 per cent. of them contained oxalate. Morris, in a series of seventy-seven stones, gives the following figures: calcium oxalate, 44.15 per cent.; uric acid, 22.07 per cent.; phosphate, 16 per cent. White of London, in a recent article, records that, in a series of twenty-four renal stones investigated, 75 per cent. contained calcium oxalate and 58 per cent. calcium phosphate. In eleven of these stones (45 per cent.) some proportion of uric acid was detected, but in all of them calcium oxalate or calcium phosphate was also present.

In the preceding figures there is a large variation in the results obtained by the different investigators. This can be accounted for because: 1. Some of the authors included in their series several stones removed from the same bladder and having the same composition. 2. In the investigations in several instances, only the incidence of one or more constituents was sought, the other elements in the stone being disregarded. However, it is noted that the later investigators found more oxalates than their predecessors.

In presenting this article it is not my intention to carry on further investigations as to the composition of urinary calculi in general, but rather to consider those stones that have been negative to the roentgen ray. It has been previously shown by various authors that certain calculi have a greater opacity than others,

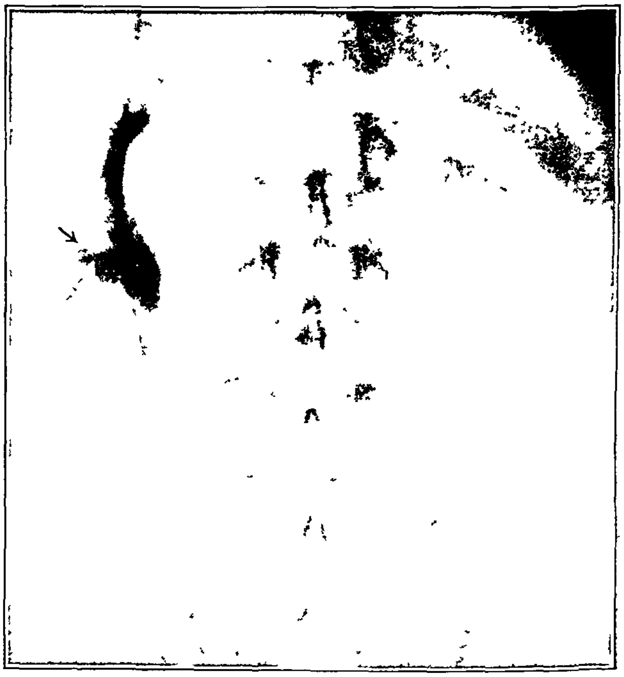

Fig 3 —Small calculus located in pelvis: Stone was composed of uric acid and was negative to ordinary roentgen ray

and also that the constituents of those stones are directly responsible for the type of shadow shown in the roentgenogram. In the two series of cases presented, roentgenograms having been negative, other means were used in the diagnosis of calculi.

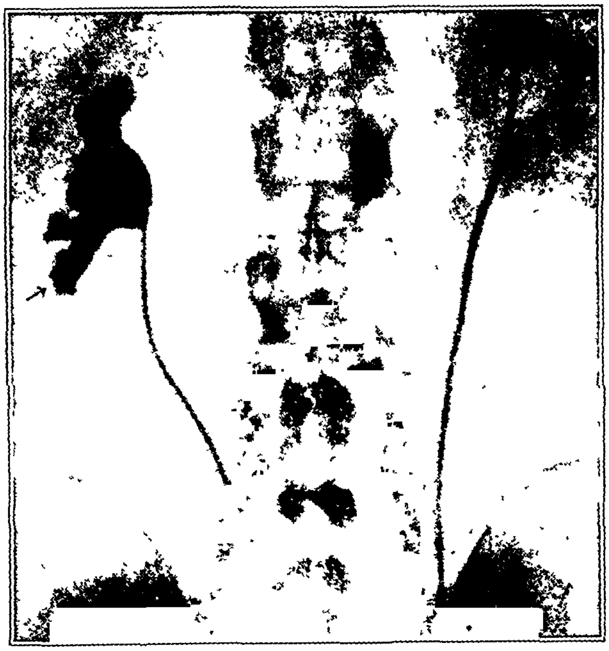

Fig. 4.—Calculus located in the lower calix: Constituents were uric acid and urate; negative before pyelography.

In considering the density of calculi, and in comparing the relative shadows cast by stones that differ in composition, there are several factors to be taken into consideration. It is known that the photographic effects of rays vary. Soft rays produce relatively too great, and hard rays relatively too little, effect on the photographic film. Irregularities of the film, secondary radiation, and exposure to heterogeneous rays are also disturbing factors. Under similar conditions the results obtained will be alike. Attempts have been made, however, to compare the relative opacity of different calculi submitted to rays at different times, varying degrees of exposure being used, and, in several instances, different apparatus. Naturally, under such conditions, no accurate conclusion could be formed.

There are certain accepted standards of radiography, proved by various investigators, as to the capacity of different bodies to absorb the rays and also the factors that affect this capacity. Some of these standards, as stated by Benoist, are as follows:

1. The specific opacity of a body for a given quality of roentgen rays and for a standard measured thickness is independent of the physical state of that body. This means that the same transparency of a body will be obtained whether it is in a solid or a liquid state.
2. The specific opacity of a body is independent of the method of grouping of its atoms or molecules.
3. The specific opacity of a body is independent of the combination of its atoms.
4. The specific opacity of a substance depends on its atomic weight.

Therefore, as a urinary calculus is composed of a number of constituents, each constituent having a different degree of opacity, then the opacity of the calculus will be equal to the total opacities of its constituents.

Table 1 contains a list of elements tabulated according to their atomic weights and also shows their absorption coefficients. A study of the table will tend to impress the fact that there is indeed a true relationship between the atomic weight and the absorption coefficient, although at present there is no accepted formula connecting these values.. It is noticeable that the opacity increases relatively much more slowly with the atomic weight in the lighter elements than in the heavy elements. Table 2 is a list of the simple constituents composing urinary calculi, arranged according to their atomic weights, and, necessarily, according to their increasing density.

Table 1.—*Relation Between Atomic Weight and Absorption Coefficient*

Element	Approximate Atomic Weight	Absorption Coefficient
Hydrogen	1	0.05
Oxygen	16	0.9
Sodium	23	1.9
Aluminum	27	3.4
Potassium	39	11.1
Calcium	40	14.4
Bromin	80	154.0
Silver	108	300.0
Iodin	127	315.0
Lead	207	569.0

Table 2—*Components of Urinary Calculi*

Hydrogen	1	Sodium	23	Sulphur	32
Carbon	12	Magnesium	24	Potassium	39
Nitrogen	14	Phosphorus	31	Calcium	40
Oxygen	16				

Combinations of the substances in Table 2 may be arranged in the same manner according to the sum of their atomic weights, and will be found to be in direct relationship to their opacity.

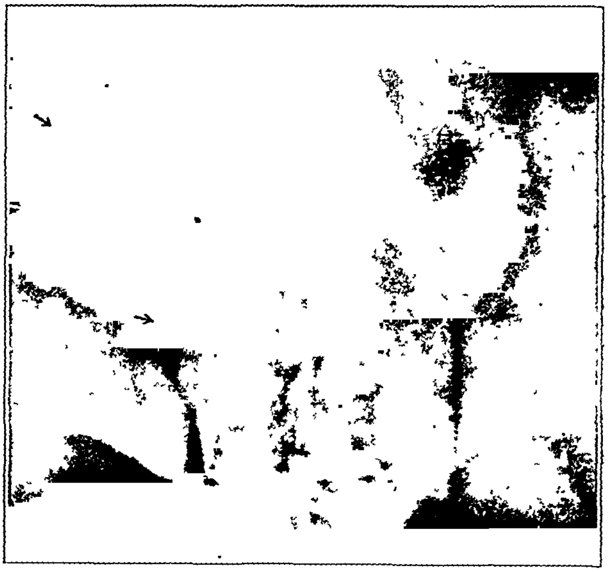

Fig. 5—Calculi of pelvis and ureter: Ureteral calculus composed of uric acid is prevented from entering bladder by stricture.

From Tables 1 and 2 one can understand why the soft parts of the body give such a poor shadow. These parts are composed of combinations of organic substances that are composed of hydrogen, carbon, nitrogen and oxygen, all of which have very low atomic weights.

OPACITY OF CALCULI

In considering the opacity of urinary calculi, we must bear in mind that the construction of the stone also plays an important part in its density. For instance, the medullary portion of a stone may be composed entirely of uric acid, and if the outer layers are poor in calcium salts or substance of heavy atomic weight, the shadow cast will be very weak, or even negative on the film. Then, again, the actual thickness of a stone will have a bearing on the type of shadow cast, although, as stated before, the larger of two stones will not necessarily reproduce the heaviest shadow, depending on the composition and the atomic weights of the constituents. Another factor in determining the opacity of a stone is its structure and, incidentally, its position, which affects the structure. That is, a stone located in a cavity or embedded in soft tissue has greater possibility for expansion than a stone that is having pressure applied on it by surrounding tissue. Thus, the first stone is more likely to be of a porous structure and will cast a shadow that is less dense than the compact calculus. In the case of the porous structure, the moisture absorbed undoubtedly plays some part in its density; because in several instances, bladder stones that had cast no shadow before removal, after dehydration had taken place, were positive to the roentgen ray, even in a pulverized condition. Therefore, we may consider that the opacity of a stone is governed by the arrangement of its constituents, by its thickness and by its structure.

Arcelin, in a comparative study of calculi, arranged a number of stones each cut to a thickness of 4 mm. on a plate, and exposed them to the roentgen rays. On examination he found the stones to be composed of the following constituents in the order of their opacity: calcium phosphate, casting the densest shadow; calcium oxalate; calcium and magnesium phosphate; ammonio-magnesium phosphate; calcium and magnesium urate; uric acid.

White, in a similar investigation, cut into cubes, each 5 mm. in thickness, stones that had previously been analyzed. The results obtained are as follows: calcium phosphate; calcium oxalate; cystin with a small amount of calcium; mixed urates; triple phosphate with a trace of calcium; xanthin with a trace of calcium; uric acid.

Table 3.—*Results in Keyes' Series of Cases*

	Positive	Erroneously Negative
Renal pelvis	32	6
Ureter	20	14
Bladder	16	12

The foregoing experiments resulted in shadows that were in conformity with the relative molecular weights and satisfy the standards of Benoist.

URINARY CALCULI UNDER DISCUSSION

As stated before, it is an accepted fact that a certain percentage of urinary calculi are negative to radiography. Keyes, in a consecutive series of cases in which stones were present, found the results given in Table 3.

After the ordinary radiography has failed to disclose stones of the urinary tract, in the presence of subjective symptoms we have several avenues of investigation. We have first of all the cystoscopic examination, which will disclose all vesical calculi, regardless of composition. For calculi of the upper urinary tract, we have the waxed tip catheter. This method in itself is liable to error, since markings on the wax are often received from other sources than stones during the operation. Finally, there is urography, which in several instances caused a previously negative stone to produce a shadow on the roentgen-ray film.

In the series of bladder cases presented in Table 4, roentgen-ray examination for stone was negative. In each case the diagnosis was made by use of the cystoscope. This series does not include stones positive to the roentgen ray.

Table 4.—*Vesical Calculi Negative to the Roentgen Ray*

Patient	Age	Duration of Symptoms	Roentgen-*Ray* Findings	Cystoscopic Findings	*Composition* of Stone
1. C F. O.*	65	5 years	Negative	Positive	Uric acid; trace of phosphatic deposit
2. G. F. S..	40	6 months	Negative	Positive	Urate, and phosphatic deposit
3. J. M.†...	55	No symptoms	Negative	Positive	Xanthin; very slight trace of calcium; phosphatic deposit
4. T. F. N..	60	1 year	Negative	Positive	Uric acid; trace of phosphatic deposit
5. J. P.‡....	48	2 years	Negative	Positive	Uric acid; trace of phosphatic deposit
6. F. R.....	50	8 months	Negative	Positive	Uric acid; trace of phosphatic deposit
7. D. F. H..	51	4 months	Nega*tive*	Posi*tive*	Uric acid; trace of *phosphatic deposit*

* Patient also had four small calculi in the membranous urethra.

† Patient had symptoms of prostatic obstruction for a period of two years.

‡ Patient gave a history of stricture for three years.

A study of Table 4 will show that in no case was the roentgenogram positive. However, in the case of the xanthin stone, there was a suspicious shadow, not unlike a defect in the film, present, although no positive diagnosis was made. This stone was located behind an enlarged prostate, and there is a possibility that it would have been revealed if it had been located in the bladder.

Age.—All the patients were of such age as might lead one to suspect pathologic changes of the lower urinary tract.

Accompanying Pathologic Changes.—It is noticeable in this series that there were some pathologic changes, such as stricture of the urethra and enlargement of the prostate. This was also true in cases not included in this paper; undoubtedly many vesical calculi are passed through the urethra while still very small, unless there is some obstruction at the bladder neck. The exceptions are those included in a diverticulum or encrusted on the bladder wall.

Chemical Composition.—All the stones were composed of uric acid or urates, which are the constituents found in previous experiments. Xanthin, with a very slight trace of calcium, was the sole exception. Failure to photograph in this case was undoubtedly largely due to the position of the stone behind the prostatic enlargement. All the stones were coated by a thin film of phosphatic deposit. Other vesical calculi examined but not included here had a similar coating but of very much greater thickness and were positive to the roentgen ray.

RENAL CALCULI

A discussion of renal calculi would necessarily include those located in the ureter as well as in the pelvis and kidney substance. Consequently, a diagnosis of a calculus located in the parenchyma is well nigh impossible without the roentgen ray. If the composition of the stone is such as to render opacity difficult, it may be possible to miss it even with repeated examinations.

TABLE 5.—*Renal Calculi Negative to the Roentgen Ray*

Patient	Age	Location of Calculi	Roentgen-Ray Findings	Diagnosis by	Composition
8. M. K....	26	Pelvis	Negative	Pyelogram	Uric acid; trace of earthy and triple phosphate
9. H. N. P.	34	Pelvis	Negative	Pyelogram	Uric acid; trace of urate; thin line of calcium oxalate
10. C. F. G.	32	Ureter	Negative	Waxed tip catheter and urethrogram	Uric acid; triple phosphate
11. C. H....	27	Ureter	Negative	Waxed tip catheter and urethrogram	Urate; trace of oxalate
12. M. F. S.	37	Pelvis	Negative	Pyelogram	Uric acid; triple phosphate
13. F. C....	29	Pelvis	Negative	Pyelogram	Uric acid; urate; trace of oxalate
14. G. S.....	33	Pelvis or ureter	Negative	Passed by urethra	Uric acid; triple phosphate
15. D. F....	30	Pelvis or ureter	Negative	Passed by urethra	Uric acid; triple phosphate.
16. C. A....	33	Pelvis or ureter	Negative	Passed by urethra	Urate; trace of phosphate

In this series, the roentgen-ray findings were negative in every case. In six of the cases a diagnosis was completed with the aid of urography. The agents used were 20 per cent. neosilvol or sodium iodid solution, 12 per cent. Without entering into a discussion as to the relative merits of either medium, I would say that in routine urography the neosilvol solution seemed to be less irritating. In all cases the measure was used as a routine. In the last three cases no diagnosis was made, but within seventy-two hours after examination the calculi were passed by the urethra.

Uric acid and urates in this series were also the chief constituents. In no case was there any marked infection, nor was there any decrease in the excretory function of the kidney. Undoubtedly, if the calculi had not been discovered at the time of examination they would have increased in size and, in the presence of infection, accumulated other urinary salts of a greater atomic weight, so that later roentgenograms would have shown a shadow. All the foregoing calculi were doubtless in the process of early formation and within a short time would have taken on the calcium salts which are the common constituents of kidney and ureter stones.

CONCLUSIONS

1. The relative opacity of a urinary calculus depends on the total molecular or atomic weights of its constituents and is influenced by its structure and thickness.
2. Some urinary calculi having constituents of low atomic weights are negative to the roentgen ray. These include stones composed of uric acid, urates and triple phosphate.
3. The diagnosis of urinary calculi should not be guided entirely by radiographic reports.
4. Cystoscopy and urography are very necessary as well as valuable adjuncts in the diagnosis of urinary calculi.

IMPACTED CALCULI OF THE URETER

TREATMENT EMPLOYED AND RESULTS OBTAINED IN SIXTY CASES *

ALEXANDER HAMILTON PEACOCK, M.D.
SEATTLE

This paper comprises a study of sixty cases of calculi that have left the kidney and become impacted in various levels of the ureter. While these cases do not form a large group, the study of them may bring out some interesting information relative to their disposition and the subsequent findings. All occurred in private practice. It is my purpose in this study to show the pathology, the symptoms, and the various forms of treatment for them, with a particular view of arriving at the best end-results. It is the impacted calculus in which we are particularly interested. Those which rapidly descend the ureter will not be considered. A number will lodge temporarily in the ureter, and then pass on into the bladder; these also are excluded. Only those which, after repeated attacks of ureteral colic, fail to move downward will be termed impacted.

ORIGIN

All ureteral stones are primarily renal. They form in the calices as a result of stasis, and the deposit of precipitated urinary salts, with pus or bacteria as a nucleus. In a large percentage of this series, the staphylococcus is present. When one sees a patient whose urine is loaded with staphylococci, immediately one should become suspicious of the presence of calculi somewhere along the urinary tract. Bacilli of the colon groups occur much less often. A calculus once formed may remain a renal stone or may become dislodged, drop into the renal pelvis, and slip down the ureter. It may reach the bladder in a few hours, or remain in the ureter for years.

PATHOLOGY

Assuming that the majority of these calculi are formed in the presence of bacteria, it is not unnatural to find a pyelitis present. This catarrhal inflammation of the pelvic mucosa does not end abruptly at the pelvic ureteral junction but extends down the lumen of the ureter. It is a continuous membrane and subject to the same infection as the pelvis. This is a point rather important to consider; namely, that there is a mild inflammatory process going on in the mucosa of the ureter. To complicate the passage of the calculus, then, we often have, first, a ureteritis, presenting inflammatory changes, irritable and easily traumatized. Continued any length of time, this could easily develop into a ureteral stricture. When Hunner first called attention to frequency of ureteral stricture, he was doubted and discredited. Today, we all know the frequency of this condition. As far back as 1902, Howard Kelly [1] wrote: "Obstruction is the generic term for any hindrance to the downflow of the urine, while stricture is specific in its designation, being limited to intrinsic narrowings due to disease of the ureteral walls. . . . Strictures are caused by an inflammation in the ureteral walls produced by commoner pyogenic cocci, by the gonococcus, and by the tubercle bacilli." When the pathology is understood, it is not so difficult to see just why some ureteral calculi become impacted. They may lodge against a stricture, and no hydrostatic or peristaltic force behind them would ever propel them into the ureter. These strictures may involve only the mucosa and the submucosa, or they may extend throughout all the structures of the ureter, and even cause periureteritis. In one case the thickness of the ureteral wall was normal except at the point of the stricture, where it measured 1 cm. from lumen to periphery. For familiar examples, let us recall the various types of strictures found in the male urethra. Certain classic points for stricture of the ureter have been described by Kelly; namely, the ureteropelvic junction, the place of crossing of the ureter over the iliac artery as it drops into the pelvis through the broad ligament in women, and the ampulla of the ureter in the bladder wall. In my experience, strictures occur anywhere along the ureter.

---

* Read before the Section on Urology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

[1] Kelly, H. A.: Stricture of the Ureter, J. A. M. A. **39**: 363-369 (Aug. 16) 1902.

It is now recognized that bacteria play an important rôle in the formation of renal calculi, because of their common occurrence in bone suppuration and chronic infection of the urinary tract. In this group, I found the various types of *B. coli-communis, Staphylococcus aureus* and *albus, Bacillus catarrhalis,* and the tubercle bacillus. One group of bacteria may be found alone, or they may be found in combination. The commonest is the colon bacillus and the staphylococcus. The presence of these bacteria were ascertained by smears of sediment taken from the kidney or ureters, and by cultures. It is a commonly known phenomenon that chronic cystitis with obstruction very frequently results in vesicle calculus, due to stasis, and obstruction to the outflow of urine. When the same conditions are present to a lesser degree in the calix and pelvis of the kidney, it is not unnatural to find the same formation taking place. It is also found that with many of these cases, a pyelitis is also present. The absence of bacteria at the time of the examination does not exclude the bacterial origin, as a pyelitis may have existed at the time the calculi were formed and subsequently cleared up.

In the cases here considered, 48 per cent. did not show bacteria at the time of examination, 27 per cent. showed staphylococcus present, 20 per cent. showed staphylococcus with colon bacilli, 4.5 per cent. showed colon bacilli, and 0.5 per cent. showed tubercle bacilli. This shows the great preponderance of the staphylococcus as it occurred singly and in combination in 47.5 per cent. of all the stone cases.

Presence of Pus.—With bacteria present, it is evident on examination that pus is apt to occur, and we find it occurring in 80 per cent. of the cases, while 20 per cent. are negative for pus or pus cells.

Hematuria.—When the microscopic character of these calculi is recalled, being composed of crystals with sharp edges, it is not unnatural that we should find blood or red corpuscles in the urine. In fact, a severe renal colic, accompanied by red corpuscles in the urine, is proof enough of the presence of a calculus, whether it is ever found or not. On making the examination, this history becomes an important finding. Seventy-three per cent. of the patients gave a history of hematuria, while 27 per cent. had no record of bleeding. In 94 per cent. of the cases, red corpuscles were found by microscopic examination. This examination should never be overlooked.

Size.—The calculi varied from 3 to 30 mm. in length. In averaging up the calculi, only the length will be considered. The average length was 8.7 mm. Those which were found at operation were mostly rough and adherent to the delicate wall of the ureter.

LOCATION

The location of the calculi in the ureter is most interesting. Seventy-six per cent. of the stones were in the lower third of the ureter, 19 per cent. in the upper third, and 5 per cent. in the middle third. It has been taught for many years that there were certain constricted portions of the ureter: namely, the ureteral pelvic junction at the brim of the pelvis, at the point in the female where the ureter traverses the broad ligament, and at the ampulla of the ureter where it joins the bladder. This I believe to be incorrect. Calculi may be impacted in any portion of the urethra. However, by far the most prevalent point is in the lower third, that portion of the ureter which runs subcutaneously into the bladder, where it is naturally protected by constricting muscle which tends to prevent regurgitation up the ureter. This location offers a strong resistance to the passage of the calculi which are descending toward the bladder. We are not surprised, therefore, to find 76 per cent. of the calculi in this portion of the ureter, where the ureter is large and elastic, and expands readily. Nineteen per cent. were lodged in the upper third. These calculi were dropped into the ureter from the pelvis, and the tube would not expand and allow them to pass farther on.

CHRONOLOGY

One of the most interesting facts brought to light was the average duration of these calculi in the ureter before they came to operation and relief. The average time of the cases we are considering was nine years. It is well known to urologists that these patients have been operated on for every imaginable condition excepting the calculus present. Every physician could recite many such instances. I shall mention just one:

A man, aged 49, had suffered with pain in his right side for nine years. It was a typical renal colic radiating into the testis. The appearance of blood was present in the urine. The patient had had four major operations: an appendectomy, two for the removal of intestinal adhesions, and a nephrotomy. The kidney had been searched for a calculus. A roentgenogram showed shadows in the upper right abdomen, which proved to be gallstones. A film of the lower urinary tract revealed a calculus in the middle third of the ureter. Catheterization of this side showed a very definite obstruction and very little urinary function. The calculus was removed by an extraperitoneal ureterolithotomy, and the pains of the last seven years have been entirely relieved.

The average distance from the bladder of the stones was 8.5 cm.

In 68 per cent. of the cases, delayed function was observed. In 12 per cent., there was a total obstruction and no kidney function. In 20 per cent., there was no impairment of the renal function noted by the phenolsulphonephthalein test.

SYMPTOMS

The youngest patient was 23 years old, the oldest patient 70, and the average age was 43. The greatest number of cases occurred between the ages of 30 and 50. Ages from 20 to 29 contained 13 per cent. of the cases; from 30 to 39 years, 34 per cent.; from 50 to 59 years, 13 per cent.; from 60 to 69 years, 8 per cent., and 70 years and over, less than 1 per cent. In other words, impacted calculi seem to cause a disease similar to gallstones, largely involving those in middle life. This may be due to overeating, sluggish habits, and the result of infection.

It was found that 96 per cent. of the calculi were solitary, the remainder showing two or three impacted calculi. These figures do not take in other renal calculi which have been passed previously.

ROENTGENOGRAMS

Demonstrations of ureteral calculi by roentgenograms are largely a question of fine roentgen-ray technic. The gas in the alimentary canal should be gotten rid of to avoid a covering of the stone with a gas cloud. The results with compression are better than those without it. Absence of all motion within the abdomen is important, as blurring has spoiled many a picture. The roentgen ray gave positive shadows in 72 per cent. of the cases. The remainder were diagnosed by means of clinical symptoms, the wax tipped bougie, and obstruction to the catheter. A catheter meeting a definite obstruction, with pathologic urine or no urinary secretion at all, always gives a splendid clue as to the point of trouble in the ureter. By counting off the centimeters on the catheter and then examining the film, we are often able to point out the calculus which would have otherwise been overlooked, as it sometimes lies behind a transverse process. Next to the ureteral catheter, the roentgenogram is the most valuable diagnostic aid.

SEX

About 80 per cent. of the patients were males, while only 20 per cent. were females. This difference is hard to explain. It is possibly due to the more vigorous life of the male, and his greater exposure to the various infections, injuries and traumatisms.

PAIN

The pain of the impacted calculi has a dual character. First comes the classic colic, very intense and conveying pain impulses along the course of the ureter, and the occurrence of sympathetic pains allied with it, as in the bladder, testes and kidney. It is produced by temporary obstruction and the painful peristaltic waves driven against the impacted calculus. This pain backs up into the kidney; after a time, the patient experiences a throbbing sensation; vomiting frequently occurs. The patient becomes pale and frequently collapses. The attacks may occur at any hour of the day or night. As a rule, the calculus is moved a trifle and some urine escapes down the ureter, thus relieving the great tension back of it. The acute colic subsides and the pain is then a dull ache in the region of the kidney. At the point of constriction in the ureter, there is frequently marked tenderness. In addition to this, there may be pain in the bladder and irritation of that organ, producing frequency and some tenesmus. Often the pain is so severe as to simulate an acute abdominal lesion, and this explains why a number of these patients have been operated on for acute appendicitis. There was a definite pain of some character in the whole series of patients; none were free of pain, and it was for this symptom that they applied for examination and relief.

The character of the pain in 74 per cent. of the cases at the time of examination was mild. In 12 per cent., the pains were moderately severe; in 14 per cent., very severe. Sixty-eight per cent. of the patients had colic in both kidney and ureter, and 24 per cent. had uncomplicated ureteral colic. The interesting factor in these figures is the large percentage of ureteral calculi which produced a simple renal colic without pain in the ureter. This occurrence is a referred pain. It is illustrated by the following case:

A man, aged 49, had suffered for three years with periodic pain and colic in the region of the left kidney, accompanied with nausea and vomiting. He had no attack until sixteen months later, when he again had intense renal colic. Roentgenograms were taken many times but did not include the whole kidney, ureter, and bladder region. On cystoscopic examination, an obstruction was found in the left ureter, 3 cm. from the bladder. A roentgenogram of the pelvis revealed an impacted calculus measuring 10 by 22 mm. Had the pain been lower, or had there been ureteral colic, doubtless the physician would have taken a picture lower down.

This case illustrates the necessity of having all roentgenograms include the whole urologic tract. A number of calculi have been missed on account of this fault in technic.

Unilateral backache was noted in 90 per cent. As a rule, this was not severe and was best described as a dull ache or a heavy feeling. A rise of temperature of 1 or 2 degrees, accompanied by mild chills, was noted in 70 per cent. of the cases. This rise in temperature indicates an obstruction of the urine with the presence of infection. As soon as the obstruction was released, either by catheterization or by lithotomy, the temperature rapidly returned to normal.

NUMBER OF ATTACKS

The number of attacks of colic and pain varied from one to many, many being implied when the patient had lost count of the number of attacks. This comprised 40 per cent. of them. The remainder averaged from two to six attacks. There was no rule to govern this, but it was surprising how frequently a patient would go a number of years between attacks, and the calculi would not move. This is explained by the urine channeling the calculus.

TREATMENT

The treatment of the impacted calculus is always a problem. The patient wishes relief from the severe attacks of colic and the dull constant pain, which more or less incapacitates him, keeps him from pursuing his occupation and thereby cuts off his income. In the second place, the impacted calculus undoubtedly injures the ureter at the point of impaction, and beyond this point causes hydronephrosis. Dilatation of the pelvis and calices result, setting up or continuing infection of the mucous membrane. This, in time, is apt to progress to the stage of pyonephrosis, with partial or total destruction of the kidney gland. It is often demonstrated by high blood chemical findings and a poor phenolsulphonephthalein showing, which has been observed in these patients. A long impacted calculus is a menace to the patient's renal function, and consequently will shorten his life. The aim of the treatment will be to free the patient from the impaction in the ureter with as little trauma and shock as possible. It has been observed that many calculi, apparently impacted, will complete the journey to the bladder without operative intervention.

Our first procedure is the dilation of the lower third of the ureter. As mentioned before, the greatest number of obstructions takes place in that portion of the ureter in the bladder wall, and just beyond it. The most efficient cystoscope for dilation is the one of the operating type; where large catheters may be used, and the thrust of the catheter is almost a straight line, occasionally meatotomy of the ureteral opening will help. Caulk has reported a number of very successful dilations of the ureter by inserting additional catheters as the ureter is dilated. This is largely a matter of skill. I have found it advantageous at times to inject liquid petrolatum into the ureter. It at least coats the calculus with oil and helps to free the adhesions, and, in my opinion, has been an aid. In the present series, this method was successful in assisting the calculus into the bladder in 50 per cent. of the cases.

Those calculi which are frankly too large to descend into the bladder, and are tightly wedged and adherent to the wall, should be removed by operation. Those in the upper third of the ureter are best exposed by a lumbar incision, the ureter being picked up and the incision made just over the calculus. Those in the middle and lower third are best reached by an abdominal incision about 5 cm. inside and parallel with the inguinal fold, the skin, fascia and transversalis muscle being cut, the peritoneum pushed toward the median line, and the ureter located at the pelvic brim. There are several points in this technic that have been found useful. Frequently the ureter is large and embedded in the posterior wall of the peritoneum, to which it is firmly attached. Some have found difficulty in locating the ureter because it was hidden behind the peritoneal retractor. It is always wise not to strip the ureter too freely, upward or downward. Its blood supply consists of little twigs along its course, and the tearing of these will devitalize the ureter or cause bleeding. It has been found that the calculi impacted well down in the pelvis near the bladder are the most difficult of all. Here there may be a stricture or an inflammatory condition of the ureteral wall, so that it has been at times very difficult to palpate the calculus. It could not be felt through the thick ureteral wall. Another circumstance which has been experienced is that rarely do these impacted calculi free themselves so that they can be milked up the ureter into a more accessible point for delivery. They seem to be adherent to the mucosa, and their sharp crystals hold on very tenaciously. It is always better to open the ureter directly above the site of impaction.

As a rule, only the outer coat of the ureter was sutured. A rubber tube will take care of the draining, which is often beneficial to the kidney above. Some of the wounds will not leak urine at all following the operation; others as a rule close within two weeks' time.

In one patient, an extraperitoneal delivery was made, and in another patient the calculus was delivered through cystotomy. This was in a man, aged 42, with a uric acid calculus at the vesico-ureteral junction. It did not show in roentgenograms, but the cystoscope revealed the calculus with its nose projecting into the bladder. The calculus measured 30 mm. in length. The bladder was opened and the calculus was lifted out of the ureter. The patient had suffered for twenty-eight years, and had been operated on several times before to relieve his cystitis.

COMPLICATIONS

Strictures.—In 18 per cent. of the cases of ureterolithotomy, marked organized strictures were found. These strictures were divided and have since been followed up by dilations with catheters and bougies. The strictures are a very serious problem, as they have a tendency to close down and entirely shut off the flow of the urine.

A man, aged 49, who had an impacted calculus and stricture of the right ureter just beyond the bladder, was treated by extraperitoneal ureterolithotomy. The wound closed nicely. A month after operation, the ureter was dilated with a No. 5 catheter and the urine was found to be normal. Six months after the operation, the patient began to complain of pain in the bladder and soreness at the lower end of the ureter. All attempts to pass the point of stricture were unsuccessful. He complained of so much pain that nine months after the first operation the right kidney was explored. It was found to be of normal size, but a very blue, large pelvis, and the ureter under great pressure were discovered. Nephrectomy was decided as the only solution for the stricture, and since that time, the patient has enjoyed good health and has been free from pain.

Another patient, who had had a right sided colic for several years, came in for examination. A calculus was located 11 cm from the bladder. On account of repeated colic, and the inability of catheters to pass the stricture, a ureterolithotomy was performed. The interesting point observed in this patient was that two soft calculi were lifted out of the strictured ureter. At this portion of the ureter, there was considerable thickening, and extending about 4 cm., the walls were indurated and not compressible; above and below this point, the ureter was apparently normal. In this case, the stricture of the ureter was primary and the calculi were secondary.

Another complication of ureterolithotomy is the establishment of a uretero-abdominal fistula.

This occurred in a woman, aged 33, who had suffered from ureteral colic for six months. An impacted calculus was located in the right ureter 10 cm. from the bladder. The patient was submitted to dilation of the ureter, but nothing would dislodge the stone. A ureterolithotomy was performed, and a calculus 15 cm. long was found impacted against a stricture. After considerable difficulty, the calculus was lifted out of its bed and delivered. The walls of the ureter were thin and partly torn across. The tear was repaired with No. 0 plain catgut sutures. The patient made an easy convalescence but has drained urine ever since. All attempts to dilate the stricture have been without avail and no urine is passing this lower segment, either by the indigocarmen test or by catheter. The ureter was embedded in inflammatory tissue, making a repair out of the question, so nephrectomy was performed.

At times, the ureters are very delicate and will not stand a great deal of trauma. The bruises and scratches of the calculus, together with the incision, have a tendency to contract the lumen and permanently mar the tube. In the majority of cases, however, the ureter repairs rapidly and has not suffered from the operation.

OPERATIVE TECHNIC

Of first importance in operative technic is an accurate location of the impacted calculus. This, as I mentioned before, is accomplished by means of a ureteral catheter and the roentgenogram. It is my belief that many ureteral calculi have been missed by operators because of uncertainty of the exact level of the stone in the ureter not being determined beforehand. Frequently a patient will allow time to elapse between the examination and the operation, so a roentgenogram should be made the day before the operation. In the second place, the operative field should be divided into three zones: the upper, the lower, and the middle third.

1. The upper zone is best reached through a lumbar incision, going through Petit's triangle, pushing aside the perineal fat, and picking up the ureter on the psoas muscle. In this region the calculus is very readily

palpated. A stitch or two of fine catgut in the outer layer will hold the ureter together and a rubber tube of No. 20 French makes a serviceable drain.

2. The middle zone is best reached through an abdominal incision, 1 inch inside the anterior superior spine, and the tissues cut are the skin, the subcutaneous fascia, and some of the fibers of the transversalis muscle. A large, self retaining tractor is placed in the wound, and the brim of the pelvis is located. The first landmark is the external iliac artery, which can be felt with its strong pulsation: crossing this large vessel and dipping into the pelvis is the ureter. On account of the many changes in its caliber and the thickness of its walls, it will sometimes be difficult to recognize. If, however, its course is accurately known, much time and labor will be saved. Again reference is made to the roentgenogram, and the calculus can be located by comparing it to the bony structure, using the crest of the ilium as a guide.

3. The lower third is more difficult. Here the ureter dips abruptly away from the operator and traverses the deep structures of the pelvis. I often encounter a greatly thickened ureter, inflammatory tissue, and lymphatic glands, these making palpation of the calculus difficult. The lower portion of the ureter cannot be brought up into the wound and is not elastic; as the lower end is firmly fixed in the bladder, extra long retractors are necessary. The Cameron light has been found to be of great service. It can be slipped underneath the ureter, and transillumination of the stone is possible. Calculi near the bladder are invariably impacted and will not lend themselves to being dislodged or moved by milking. As a rule, time is saved by exposing the ureter all the way to the bladder and incising directly over the calculus. A transperitoneal exposure of the ureter is rarely indicated unless intra-abdominal work has first been performed and the calculus has been located secondarily. In closing up the wound, a drainage tube is always inserted.

SUMMARY

1. While many ureteral calculi will pass through the ureter and be safely conducted to the bladder, a number of them will become impacted in the ureter.

2. They are held in the ureter very often by such pathologic conditions as stricture, the size of the calculus, or the rough and crystal-like surface of the stone.

3. The impacted calculi often remain in the ureter for years, and in this series of cases the average length of time was nine years.

4. A calculus, once impacted, blocks off the urine, produces pain, pressure, dilatation of the ureter and renal pelvis, keeps up inflammation of the mucous membrane, and in time impairs the function of the kidney.

5. These impacted calculi cause the patient to suffer intermittent or continuous pain for years, constantly threatening him with colic; as a result, the general health is markedly impaired.

6. Stricture of the ureter plays a considerable rôle in the impaction of the calculi, being found in 18 per cent. of the cases.

7. Contrary to previous teaching, I have not found a normal constriction of the ureter except in the lower third, where the ureter travels through the bladder wall.

8. The staphylococcus plays an important rôle in the formation of the stones, as it was found in 47.5 per cent. of all the stone cases.

9. Hematuria, either as microscopic or as red corpuscles, occurred in 94 per cent. of the cases.

10. Sixty-seven per cent. of all the impacted calculi were in the lower third of the ureter.

11. Impacted calculi are apparently a disease of middle life, the average age of the patients being 43 years.

12. In 96 per cent. of the cases, the calculi were solitary.

13. Ureteral dilation should be attempted first, as this method was successful in 50 per cent. of the cases.

14. Extraperitoneal ureterolithotomy should be performed when ureteral dilation has failed.

639 Stimson Building.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SHEA AND PEACOCK

Dr. William E. Lower, Cleveland: I have not been as successful as some surgeons have been in coaxing these stones down by manipulation. In the case of an impacted stone, I think it is a mistake to wait too long before operating. In many cases the stone will not pass before definite damage has been done to the kidney. I try to remove the stone by a muscle splitting operation. A straight incision in the back instead of the oblique incision will often make it possible to remove a stone from the upper end of the ureter. It is possible to remove many of these stones through a small incision, although I do not recommend too small an incision if it increases traction on the wound. If there has been much periureteral inflammation, the ureter should be moved as little as possible. If the stone is in the kidney pelvis, it can often be removed without manipulating the kidney: it is better to take the operation to the stone rather than to manipulate the kidney and ureter unnecessarily.

Dr. W. C. Quinby, Boston: I have had no experience with the analysis of stones as regards their shadow casting qualities, except in those instances, which we see rather more often than in the past, in which the stone consists almost entirely of cystin. There have been several cases in my clinic of cystin stones, which were found by the negative shadows cast in the roentgenray film. If one feels that there is a possibility of such a condition being present, I think it is wise to have the urine examined by the chemist for cystin. Cystinuria is a readily demonstrable condition. I wish to congratulate Dr. Peacock on his excellent presentation, in which I was much interested. I, too, feel very strongly that the manipulations that attempt to get the stone to pass by the normal passages are frequently overdone. The trauma and damage to the kidney that may follow too zealous attempts are very real. I have came to the point at which, if the dilation of the ureteral orifice, followed by some slight manipulation, fails, I desist from further manipulation and operate forthwith. It was mentioned by Dr. Peacock and Dr. Lower that one may sometimes find a large amount of periurethritis; in one of these instances, I was compelled to resect from 1 to 1½ inches of the ureter—the kidney being too good to be sacrificed—followed by an end to end suture. There was no leakage following the suture, and later the ureter was demonstrated to be patent. I have seen only one or two instances like this, but feel that we should use this procedure more in the future than we have in the past. There is one point in the delivery of stones that some may overlook. If the ureter is lifted far from its bed in getting the stone out, it is very important to see that it is put back in place before the wound is closed. I have had to reenter the field on some of these occasions, because of postoperative complications due to angulated ureter.

Dr. Daniel N. Eisendrath, Chicago: I agree with Drs. Lower and Quinby that one should not wait too long before ureterotomy is performed in cases in which nonoperative methods have been unsuccessful. At times there is such a severe febrile reaction after dilation of the ureter in these cases as to necessitate a nephrectomy. I have recently had such an experience and learn that an experienced urologist was obliged to remove the kidney in four such cases In regard to the technic of operative removal of calculi impacted in the juxtavesical and intraparietal portions of the ureter, we should always make an incision sufficiently large to afford a visual exposure of the point of impaction. A fairly large percentage of cases are complicated by stricture formation, and irreparable damage can result from incision into the ureter by sense of touch alone. I have employed a series of traction fine catgut sutures, beginning at the brim of the true pelvis and passing through the outer coat of the ureter. These enable me to expose successively deeper and deeper portions of the ureter by changing it from a curved tube into a straight one, so as to incise under guidance of the eye. I should like to have Dr. Peacock tell us whether he thinks that the stricture of the ureter in these cases is primary and the calculus secondary, or vice versa; i. e., is the stricture due to decubitus following impaction of the calculus?

Dr. R Arthur Hooe, Washington, D. C.: I will mention a case I recently saw that would serve well to illustrate the importance, as well as the difficulty, sometimes encountered in distinguishing between intra-ureteral obstructions and those due to pressure from without. This woman had had a pelvic operation some ten years previously, and presented symptoms of urinary obstruction. The point of the catheter arrested just within the ureter was shown by roentgenogram to be in contact with a rather large shadow, the size of the end of a thumb. After injection through the catheter of 15 per cent. sodium iodid, a second exposure showed the ureter so completely drawn around the first shadow as almost to encircle it. A laparotomy was performed, and a large body was found pushing into the broad ligament, which was tightly bound down. The pelvis was a mass of adhesions. After the mass had been elevated, the catheter passed easily to the kidney pelvis. Regarding ureteral calculi, I appreciate what Dr. Quinby has said; but as a result of a number of recent experiences, one, notably—the passage of a very large calculus by a short and very stout person who wished to avoid operation—I am inclined to believe that while in many cases operation is necessary, yet in another large group temporizing is the wisest procedure.

Dr. Ralph L. Dourmashkin, New York: The point I wish to discuss is what determines complete blockage of the kidney and when we should operate. My remarks are based on the study of 122 cases. There are two types of cases. In one the patient is acutely ill; there is an acutely impacted calculus in the ureter and an acutely infected kidney. In such cases, too much temporizing may lead to disastrous results, and the stone, as a rule, must be removed by operation. In the other type we are dealing with a chronic impaction of the stone. I have seen cases in which the stone has been impacted for many years and yet there was no renal infection, the kidney specimens of urine showing but a few pus cells, although the function of the kidney had suffered a great deal. What saves the kidney in these cases? If we examine the stone removed either by an operation or by intra-ureteral manipulations, we find a definite groove or a notch on the surface of the stone, which is nature's method of maintaining drainage, and that is the thing that saves the kidney. In these cases, although we are unable to pass a catheter by the stone, we are still able to collect urine through the catheter below the obstruction, the urine finding its way through the groove. I believe that some of these cases should be treated conservatively, and the patient given the benefit of cystoscopic manipulations. In this series the stones were removed by intra-ureteral manipulations in eighty-three cases, or 68 per cent. Eighteen patients, or 14.7 per cent., were operated on. It is said that the presence of a stone in the ureter is due to stricture. In a number of my cases the stones were removed by manipulations, the ureter being dilated to Size 20 with the tunneled bougies that I described some time ago. Certainly the patients did not have any strictures after such a dilation, and yet they continued to manufacture stones.

Dr. Charles S. Vivian, Phoenix, Ariz.: I suppose that after having a stone pass, by operative procedure or manipulation, it is well to pass the catheter, for subsequently I have found developing stricture. A patient had all the evidences of a retroperitoneal accumulation of pus. The abscess was drained retroperitoneally, and no stone was found. After the acute condition had subsided, she spontaneously passed a stone as big as the end of my index finger. The interesting point was that I catheterized her subsequently and found that the urine from that kidney contained as much urea as that from the kidney on the other side.

Dr. A. L. Chute, Boston: It has been a great pleasure to listen to these two papers. Dr. Peacock showed slides in which, in certain cases, a roentgen-ray examination had not been made of the entire urinary tract. It seems to me it is most unwise not to take in the whole tract whenever we use the roentgen ray; we so frequently find the underlying lesion in the part we did not take. I think we are, as a rule, unwise to leave a ureteral stone in the presence of pus and pain. There are some instances of small stones low in the ureter in which one can open the ureter some little distance above the stone, reach down with a long forceps, which some man in Rochester has devised, and work the stone up the ureter. There are instances, of course, in which this cannot be done; but, when it is possible, I think it is a better procedure than dissecting the lower end of the ureter free or opening blindly onto a stone in the lower end of the ureter.

Dr. W. G. Schultz, Tucson, Ariz.: To illustrate the dangers we sometimes get into, I will recite the case of a patient who had been diagnosed as having appendicitis. Finally a roentgen-ray examination disclosed a stone in the ureter about 5 cm. from the bladder. The stone was about the size of a bean, and numerous attempts to pass it with catheters and dilators failed. I used a Bransford Lewis dilator and, in attempting to remove it, found that I could not get it out. I made a roentgenogram and found that the dilator had acted as a forceps rather than as a dilator and had engaged the stone. I had to remove it by firm, gentle pressure and it took about forty-five minutes. The patient made an uneventful recovery and developed no complications.

Dr. Daniel E. Shea, Hartford, Conn.: One point I wish to bring out is the necessity of pyelography. I think we have reached the point at which we recognize that in skilled hands today the danger is practically nil. I hope in presenting this article that I can impress on the men who are not in the specialty of urology the necessity of a urologic study, when stone is suspected to be anywhere in the urinary tract, rather than depend on an ordinary roentgenogram.

Dr. Alexander H. Peacock, Seattle: Dr. Lower spoke of transperitoneal exposure, but I myself prefer the extraperitoneal method. I can see no harm in cutting a few muscles along the transversalis. Dr. Eisendrath spoke of a good exposure and of illumination. One of the best things I know of is the Cameron light. It gives excellent illumination, and can be used just where one wishes. The query was put, "Which is primary, calculus or stricture?" This is a matter of speculation. It seems to me that if calculus is a primary affair, stricture will result from the impaction. I had the pleasure of spending a day in Baltimore with Dr. Hunner, and found him to be one of the finest men in the world. He demonstrates many "hangs," but in nine tenths of them, the hang occurred in the intramural portion of the ureter. I feel that possibly he is making a faulty interpretation by his technical methods. In regard to pyelographic kinks, many are simply those of position, produced by a rigid catheter.

Full-Time Obstetrician.—I believe that the Rotunda Hospital, Dublin, owes very much of its high reputation to the fact that the master is given a house actually in the hospital, and therefore, no matter how big his outside practice may be, he is of necessity in the hospital for, say, sixteen out of twenty-four hours; further, he is in sole charge of the hospital. A professor of midwifery (not resident in a hospital) who has to earn his livelihood in private practice is very greatly handicapped; the most he can hope to do is to attend for routine work a few hours each morning and be available for major emergencies; in the latter case (being human) he is always anxious to get back to his practice, and cannot be expected to devote the time necessary for watching cases, if active measures are at all applicable; nor has he the time to give to research. The plan of appointing whole-time professors is equally sound, and while I believe that the professor's services should be available for any one in his district, the fact of his being financially independent of practice is of the utmost importance to the efficiency of his hospital.—Tottenham, R. E.: *Irish J. M. Sc.*, November, 1925, p. 524.

THE INFLUENCE OF FOCAL INFECTIONS *

D. J. McCARTHY, M.D.
Professor of Medical Jurisprudence, University of Pennsylvania School of Medicine
PHILADELPHIA

In studying the influence of focal infections on the human organism, we should fully realize that we are dealing largely with theoretical considerations and not with a definite, demonstrable fact or series of facts subject to a testing process, such as the pathologist or bacteriologist carries out in a laboratory experiment.

Any attitude on this subject, necessarily, must be largely a matter of impression on the part of the investigator, tinged somewhat by his state of mind toward the problem under consideration. Notwithstanding that this paper is the result of a careful analysis of 500 of my own cases, all studied in detail by one clinician, the opinions in reference to the influence of the focal infections, even in this group, are the impressions made on me by the results obtained in treatment, and are by no means facts, or to be taken as complete conclusive evidence of the direct causative relationship of focal infections to nervous or mental disease.

I do not mean to imply, on the other hand, that I do not have definitely formed conclusions in my own mind on this subject, but these again are influenced by my attitude toward both the neuroses and the psychoses. *I lay it down as a fundamental principle of therapeutics in mental and nervous diseases that, unless we have a definite theory of disease to work on, we need not expect results; to treat a mental state by drugs or psychotherapy, is to do little less than the Christian scientist would do with the same cases.*

I hold that a man or woman who was sane, had always been sane up to one month ago and is now insane, so insane, indeed, that he or she is in grave danger of confinement to an insane asylum, must have some real cause for this condition, and that this cause must be a definite chemical poisoning, either bacterial or visceral in nature.

MEDICAL INSANITY

The thinking psychiatrist has come to view thought as something like the "heat" produced by muscular activity, as a manifestation of the action of the blood on the cerebral tissues in its passage through them, and not as some function inherent in the cells of and by themselves. In this sense, the brain becomes an organ for the registration of thought rather than for the production of something original. It is very much as if the liver said, "I will produce yellow or green bile." The thought processes are the products of chemical change with resultant energizing manifestations produced by the circulation of the blood through the brain tissues, and this thought process depends on two factors: the chemical composition of the blood, and the type of cell on which it acts. If this cell is a normal, healthy cell, we may expect a thought reaction within the normal limits; if it is decadent or diseased, the reaction will vary with the type of disease. This becomes of importance in the senile brain, the arteriosclerotic brain, the brain diseased by syphilis, sleeping sickness, etc. Here, also, we must consider the defective brain due to birth, to development and to heredity.

From the point of view of the adolescent psychoses, which present the great problem of insanity, in which inherited influences can be traced in less than 50 per cent. of cases, and in which we may assume, in a large majority of cases, a normal brain structure, chemical changes in the blood become of the greatest importance. These may be in the nature of artificial chemicals introduced from without, as in acute alcohol poisoning, opium, cocain, cannabis indica, lead carbon monoxid gas, etc.

In studying insanity, we are much more interested in the less well defined chemical changes introduced from within by disease of the heart, lungs, kidneys, liver, pancreas, the bone marrow, the spleen, the sex organs, and by that very important and less well understood group of glands of internal secretoin, the thyroid, the pituitary, the suprarenal, and the deranging effect of these on the chemistry of the other viscera mentioned above. As a rule, we have various and complex reactions of one on the other of the foregoing, because we lay it down as a rule of pathologic physiology that we cannot have a derangement of function of any one of the vital organs of the body, without some, and usually serious, derangement of function of all the other vital structures. When we add to this the derangement of the physical constitution of the blood in the severe anemias, we have still a further complicating factor.

To realize how complex a situation we are dealing with, one needs only to study an advancing case of fatal tuberculosis to the prelethal mental changes and the final fatal delirium. One can often, in these cases, study at first very subtle mental reactions—euphoria, advancing to depression, to suspicion and to delusions of persecution, proceeding to the last final delirium.

Cerebral anemia is associated usually with unrest, apprehension, suspicion and delusions of persecution. I have a case of a highly cultured woman, aged 65, who has a severe disease of the heart muscle, with low blood pressure. If she remains in bed, she is of absolutely normal, even high grade normal, mentality. If she tries to get out of bed and be up and about, she develops delusions of persecution. Having a full insight into this condition of mind, for several years she has refused to get out of bed, preferring the discomfort and disadvantages of the bedridden to the horror of disturbed mentality. Here we might say we have a case of purely mechanical mental derangement, but we must keep in mind that, with such a heart, the kidney function cannot be normal, nor is it likely that the liver and other organs being deprived of a full supply of blood, can be absolutely normal in function.

In tuberculosis in which anemia exists, we must add the effect of low blood pressure, the intoxication from the tubercle bacilli, the effect of complicating pus-producing organisms as the case advances, the disturbance of the ductless glands, and, secondary to this, the effects of the derangement of function of the spleen, the kidneys, the gastro-intestinal tract and other factors. It is evident how complex is the condition with which we are dealing. We all know how a small disturbance of liver function, which we call biliousness, affects us: the feeling of mental heaviness, the slight headaches, the mental depression, and the mental clumsiness we experience. The psychiatrist realizes how chronic liver disease in the sensitized person is apt to produce a incision sufficiently large to afford a visual exposure of the point of impaction. A fairly large percentage of cases are complicated by stricture formation, and irreparable damage can result from incision into the ureter by sense of touch alone. I have employed a series of traction fine catgut sutures, beginning at the brim of the true pelvis and passing through the outer coat of the ureter. These enable me to expose successively deeper and deeper portions of the ureter by changing it from a curved tube into a straight one, so as to incise under guidance of the eye. I should like to have Dr. Peacock tell us whether he thinks that the stricture of the ureter in these cases is primary and the calculus secondary, or vice versa; i. e., is the stricture due to decubitus following impaction of the calculus?

---

* Read before the Section on Stomatology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

Dr. R. Arthur Hooe, Washington, D. C.: I will mention a case I recently saw that would serve well to illustrate the importance, as well as the difficulty, sometimes encountered in distinguishing between intra-ureteral obstructions and those due to pressure from without. This woman had had a pelvic operation some ten years previously, and presented symptoms of urinary obstruction. I feel that possibly he is making a faulty interpretation by his technical methods. In regard to pyelographic kinks, many are simply those of position, produced by a rigid catheter.

Full-Time Obstetrician.—I believe that the Rotunda Hospital, Dublin, owes very much of its high reputation to the fact that the master is given a house actually in the hospital, and therefore, no matter how big his outside practice may be, he is of necessity in the hospital for, say, sixteen out of twenty-four hours; further, he is in sole charge of the hospital. A professor of midwifery (not resident in a hospital) who has to earn his livelihood in private practice is very greatly handicapped; the most he can hope to do is to attend for routine work a few hours each morning and be available for major emergencies; in the latter case (being human) he is always anxious to get back to his practice, and cannot be expected to devote the time necessary for watching cases, if active measures are at all applicable; nor has he the time to give to research. The plan of appointing whole-time professors is equally sound, and while I believe that the professor's services should be available for any one in his district, the fact of his being financially independent of practice is of the utmost importance to the efficiency of his hospital.—Tottenham, R. E.: *Irish J. M. Sc.*, November, 1925, p. 524.

THE INFLUENCE OF FOCAL INFECTIONS *

D. J. McCARTHY, M.D.
Professor of Medical Jurisprudence, University of Pennsylvania
School of Medicine
PHILADELPHIA

In studying the influence of focal infections on the human organism, we should fully realize that we are dealing largely with theoretical considerations and not with a definite, demonstrable fact or series of facts subject to a testing process, such as the pathologist or bacteriologist carries out in a laboratory experiment.

Any attitude on this subject, necessarily, must be largely a matter of impression on the part of the investigator, tinged somewhat by his state of mind toward the problem under consideration. Notwithstanding that this paper is the result of a careful analysis of 500 of my own cases, all studied in detail by one clinician, the opinions in reference to the influence of the focal infections, even in this group, are the impressions made on me by the results obtained in treatment, and are by no means facts, or to be taken as complete conclusive evidence of the direct causative relationship of focal infections to nervous or mental disease.

I do not mean to imply, on the other hand, that I do not have definitely formed conclusions in my own mind on this subject, but these again are influenced by my attitude toward both the neuroses and the psychoses. I lay it down as a fundamental principle of therapeutics in mental and nervous diseases that, unless we have a definite theory of disease to work on, we need not expect results; to treat a mental state by drugs or psychotherapy, is to do little less than the Christian scientist would do with the same cases.

I hold that a man or woman who was sane, had always been sane up to one month ago and is now insane, so insane, indeed, that he or she is in grave danger of confinement to an insane asylum, must have some real cause for this condition, and that this cause must be a definite chemical poisoning, either bacterial or visceral in nature.

MEDICAL INSANITY

The thinking psychiatrist has come to view thought as something like the "heat" produced by muscular activity, as a manifestation of the action of the blood on the cerebral tissues in its passage through them, and not as some function inherent in the cells of and by themselves. In this sense, the brain becomes an organ for the registration of thought rather than for the production of something original. It is very much as if the liver said, "I will produce yellow or green bile." The thought processes are the products of chemical change with resultant energizing manifestations produced by the circulation of the blood through the brain tissues, and this thought process depends on two factors: the chemical composition of the blood, and the type of cell on which it acts. If this cell is a normal, healthy cell, we may expect a thought reaction within the normal limits; if it is decadent or diseased, the reaction will vary with the type of disease. This becomes of importance in the senile brain, the arteriosclerotic brain, the brain diseased by syphilis, sleeping sickness, etc. Here, also, we must consider the defective brain due to birth, to development and to heredity.

From the point of view of the adolescent psychoses, which present the great problem of insanity, in which inherited influences can be traced in less than 50 per cent. of cases, and in which we may assume, in a large majority of cases, a normal brain structure, chemical changes in the blood become of the greatest importance. These may be in the nature of artificial chemicals introduced from without, as in acute alcohol poisoning, opium, cocain, cannabis indica, lead carbon monoxid gas, etc.

In studying insanity, we are much more interested in the less well defined chemical changes introduced from within by disease of the heart, lungs, kidneys, liver, pancreas, the bone marrow, the spleen, the sex organs, and by that very important and less well understood group of glands of internal secretoin, the thýroid, the pituitary, the suprarenal, and the deranging effect of these on the chemistry of the other viscera mentioned above. As a rule, we have various and complex reactions of one on the other of the foregoing, because we lay it down as a rule of pathologic physiology that we cannot have a derangement of function of any one of the vital organs of the body, without some, and usually serious, derangement of function of all the other vital structures. When we add to this the derangement of the physical constitution of the blood in the severe anemias, we have still a further complicating factor.

To realize how complex a situation we are dealing with, one needs only to study an advancing case of fatal tuberculosis to the prelethal mental changes and the final fatal delirium. One can often, in these cases, study at first very subtle mental reactions—euphoria, advancing to depression, to suspicion and to delusions of persecution, proceeding to the last final delirium.

Cerebral anemia is associated usually with unrest, apprehension, suspicion and delusions of persecution. I have a case of a highly cultured woman, aged 65, who has a severe disease of the heart muscle, with low blood pressure. If she remains in bed, she is of absolutely normal, even high grade normal, mentality. If she tries to get out of bed and be up and about, she develops delusions of persecution. Having a full insight into this condition of mind, for several years she has refused to get out of bed, preferring the discomfort and disadvantages of the bedridden to the horror of disturbed mentality. Here we might say we have a case of purely mechanical mental derangement, but we must keep in mind that, with such a heart, the kidney function cannot be normal, nor is it likely that the liver and other organs being deprived of a full supply of blood, can be absolutely normal in function.

In tuberculosis in which anemia exists, we must add the effect of low blood pressure, the intoxication from the tubercle bacilli, the effect of complicating pus-producing organisms as the case advances, the disturbance of the ductless glands, and, secondary to this, the effects of the derangement of function of the spleen, the kidneys, the gastro-intestinal tract and other factors. It is evident how complex is the condition with which we are dealing. We all know how a small disturbance of liver function, which we call biliousness, affects us: the feeling of mental heaviness, the slight headaches, the mental depression, and the mental clumsiness we experience. The psychiatrist realizes how chronic liver disease in the sensitized person is apt to produce a

---

* Read before the Section on Stomatology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

chronic mentally depressed state. Here, while the condition is apparently simple, we are dealing with many and complex factors. And so again in the infectious and febrile deliria and psychotic states, we are dealing with extremely complicated factors of body and blood chemistry acting on the cells of the brain, producing in the normal brain simple delirium, and, in the diseased or sensitized brain, complex mental states.

If a man drinks a pint of alcohol, it will act on his kidneys if they are normal in one way, and if damaged by previous disease in an entirely different way, and often in a varying way, depending on the nature of the bacteria or its toxins producing the previous damage.

In the intricate brain function not only does the alcohol play on the strings of this delicate instrument, but the tune produced may be one of harmony or discord, depending not only on the physical damage, but also on the many residual impressions retained in the cell memories, of all kinds of shocks and instincts and pain impressions long out of the field of consciousness of the individual. These are mixed in the confused delirious states. They are difficult to understand, unless by a detailed study in the relatively normal state, all of those past and forgotten ideas that went to make the character whole are revealed. When we take a running, moving, mental picture of the ideas formed and concealed from the threshold of thought, in infancy, to the threshold of adult life, at adolescence, and link this up to disease processes that disturb the nutrition of the growing brain and alter its structure and function, in addition to splitting, at times, the personality over sex and other matters, we gain a more complete idea of what goes to produce that derangement of function that leads to conduct disorders that are, and also at times are not, insanity but are distinctly pathologic.

Tuberculosis in infancy, taking two or more years for adjustment, arrest or cure, interferes with the nutrition of the developing brain. To this add an intoxication, chemical in nature, due to disorder of function of the heart and circulation; a catarrh of all the mucous membranes, especially of the gastro-intestinal tract; disorder of the liver function; weakness of the nutritional stream to brain and viscera by anemia, more or less marked, and a grave strain leading to exhausting defect in the ductless gland structure in its defensive fight against the chronic disease, and the result is low blood pressure, a long, lanky, flat and often deformed chest, a low faulty position of the body viscera, flatfoot, etc. The central and peripheral reflexes and reactions are exalted and sensitized. Through childhood, ill health is likely to lead to introspection and a splitting of the personality, an asocial tendency, a suspicious, querulous personality. When we come to adolescence, when the machine is changed in its main function from one of growth to one of reproduction, the faultily nourished brain is asked to stand the brunt of an intoxication from a damaged ductless gland system which, overwhelmed by its efforts for defense, is inadequate to the demands of the change forced on it, and fails in the critical position it is asked to take.

These factors, therefore, including (*a*) the physical factors, (*b*) the chemical factors, (*c*) the growth factors, (*d*) the endocrine factors, (*e*) the faulty physiologic adjustments and (*f*) the faulty environment in a given personality that has not the physical resistance and recuperative power to swing back to a relative normal, represent the moving clinical picture of a partly or fully formed adolescent psychosis.

What influence has focal infection in this process of intoxication? Can a focal infection in a tooth cause insanity or neurasthenia or psychoneurosis? In my opinion, this is highly improbable, if not impossible, in the normal person, even though he has a vicious heredity, in reference to nervous or mental disease. I am fully aware of the reasoning that a streptococcic infection from the teeth may set up a vicious inflammatory rheumatism, but here again I question whether there is not some underlying disturbance of metabolism whereby the focal infection may precipitate a carbohydrate imbalance.

When we are dealing with the neuroses and psychoses, we are face to face with an entirely different situation. Here we may not expect a simple cause to produce such a complex result as an adolescent psychosis.

In studying this subject, I have taken the facts and separated them from the theoretical considerations.

In 120 cases of psychosis, we find the weight to be deficient in thirty-eight cases; the general condition of the patient to be below par in seventy-nine cases; involvement of the thyroid gland in twenty-nine; involvement of the endocrine system in fifty-seven; lowered blood pressure states in forty-four; focal infections in the teeth in sixty-one; tonsils in eighty-seven, and old or new pulmonary lesions in sixty-three.

Merely because we find focal infections in more than 60 per cent. of these cases are we justified in assuming that the focal infection is the cause of the psychosis? I do not think we are so justified.

Are we to assume that focal infections acting on a low blood pressure state are the cause of the disturbed mental condition? I do not think so. As this is a theoretical consideration, it must be faced as a theory separated from the facts.

How are we to measure the influence of the underweight factor; the underpar condition; the frequent, old, pulmonary lesions; the visceroptosis, etc.? Certainly, when dealing with a scientific problem, we should treat it in a scientific manner; and we are not justified in selecting some factors and discarding others, or, indeed, in discarding any factor before us.

If we analyze the weight factor, we find in 50 per cent. of the cases that the patient has been underweight from childhood.

We have no definite earlier records of the arterial hypotension, but here again we may assume that this is the natural and chronic condition of the individual.

As to the conditions obtaining in the endocrine sytsem at the time of adolescence, it may be assumed that these are in all probability not inherent from early childhood. They may be developmental conditions which have arisen at the time of, or some time previous to, the acute mental disturbance.

Focal infections may or may not be chronic. Infections in the tonsils may be active through childhood and adolescent life. It is the rule rather than the exception to find in this group a history of repeated attacks of tonsillitis or quinsy. The focal infection factor may be active in its effect on the organism, or it may be passive up to a time of reduced vitality, when it may cause a physical or nervous reaction. In any given case, it is difficult, if not impossible, to trace which of these two states exists or when a latent condition becomes active.

Focal infections in the teeth and the gums are much more definite. Here, there is usually some record of the care of the teeth. The frequency of focal infections from this source increases as life advances beyond the adolescent period. The most frequent source of infection at or preceding this time of life is found in the unerupted wisdom teeth. As life advances, permanent bridge work, neglected or poorly filled teeth and advanced pyorrhea become increasingly frequent in our statistics.

When we come to determine how focal infections act in order to produce disease conditions of the mind, we are forced to study their method of effecting disturbance of function or of producing disease of other viscera. Here again we are forced away from the facts into the realm of theory. That focal infections, when active, are associated with an endocrine reaction, more particularly in the thyroid function, will be admitted, I think by any clinician of wide experience. The favorable reaction of hyperthyroid states in the adolescent to removal of focal infections is evidence of this. We may assume, on account of the interrelationship of function and action of the various ductless glands, a reaction, to some extent, in the pituitary, at least, and probably also in the suprarenals and gonads. The effect of focal infection on the myocardial function may be direct or indirect through the pituitary-thyroid function. In 60 per cent. of the cases, we have found the myocardial function faulty. This may be considered as evidence of actual physical damage to this organ. Is it caused by the focal infection factor? Here again this problem of internal medicine has hardly even been considered by the clinicians. The same is true to a less extent of the relation of focal infection of teeth, tonsils, sinuses and gallbladder infection to the liver function; to the kidney function, secondary to the initial lesions, and of the anemic states that have been from time to time linked up with infections in the mouth and the upper respiratory area.

The best evidences we have of the effect of focal infections on the heart function are the pulse and blood pressure reactions shown in the effort test, to focal infections, and the disappearance of these phenomena when the focal infection is relieved. Cardiac arrhythmias are not infrequent in active focal infections. Subjective symptoms of palpitation (tachycardia), substernal pressure and precardial distress are not infrequent. From an analysis of the literature on these subjects, it becomes evident that the time has arrived for definite information on a subject much talked about, but with little evidence on which to base reasonable conclusions. The effect of focal infections on the kidney function, as far as I have been able to determine, is purely secondary to the cardiac reaction.

Do the focal infections act directly on the central nervous system, on the brain, in the production of mental disease? In the vast majority of cases, I think this is a minor factor, if it acts at all. There are, however, cases in which the evidence is in favor of a direct action. This is particularly true in the chorea insaniens group. A patient now under my care, a boy, aged 17, 6 feet (183 cm.) tall, weighing 130 pounds (59 kg.), had an attack of quinsy three months ago. In six weeks, he lost 30 pounds (13 kg.). For the last four weeks, he has had a well defined Sydenham's chorea with mental symptoms. The natural assumption would be to link up the chorea and mental symptoms with the focal infections, and I feel quite certain that the chorea was the direct result of the focal infection on the cerebral tissues. One might also add that the mental symptoms were the direct effect of the tonsil infection. A general physical survey revealed an old pulmonary lesion in the right upper lobe; the thyroid gland diminished in size and of increased consistency; systolic blood pressure, 100; diastolic, 60. The very marked loss of weight and strength, the old tuberculosis and the endocrine imbalance had to be considered as factors in the mental picture, and equally so in the therapy of the case. I did not think it advisable in this case to remove the tonsils for fear of precipitating a more serious mental state. An infected tooth was removed and a process of upbuilding instituted. In one month, he has gained 14 pounds (6 kg.). The chorea has almost disappeared, but the mental picture is becoming definitely fixed into an adolescent psychosis with a neurosexual splitting of the consciousness. With his general vigor improved, we are now prepared to remove the tonsils. In this case I expect a favorable result. I quote this as a type of case in which the focal infection acts both directly and indirectly on the brain tissues, already disturbed, however, by other chronic pathologic factors.

Focal infections, if severe, would act as any other continuing infection, both directly and indirectly, on the nervous system of the growing child. Most of the teeth infections and, for the most part, the tonsil infections, act on an already damaged body chemistry.

My working theory of the relationship of the focal infections to the psychoses and neuroses is as follows:

A. Severe bacterial and prolonged infections, such as tuberculosis or syphilis in childhood, causing a strain on the endocrine defense system at a time when its function is required for growth, leads to faulty nutrition throughout childhood, with underweight, low blood pressure and a sensitized nervous system.

B. When adolescence is reached, the endocrine system, whose major function was one of the control of the growth process, is now suddenly overburdened with the new function of reproduction.

If at this time, when the endocrine and nervous systems are overburdened and overstrained with the functional turnover of adolescence, a focal infection is added, for which there is no defense, the whole body chemistry is deranged, with a toxic physical and mental picture we call dementia praecox or adolescent psychosis.

I believe that in the majority of these cases, the removal of all focal infections becomes one of the most important therapeutic measures; this alone, however, is rarely sufficient and should be considered with rest, occupation, mental training, good nursing, and an effort to get a normal functioning of all the viscera.

CONCLUSIONS

1. Focal infections in the upper respiratory tract are present in a sufficiently large percentage of cases of the psychoses and neuroses to warrant the assumption of a causal relationship between the focal infections and the disease conditions of the nervous system.

2. Focal infections of and by themselves are probably the cause of the psychotic or psychoneurotic condition in only a relatively small percentage of cases.

3. In the vast majority of cases, the focal infections process acts on an already existing condition of undernutrition, anemia, endocrine imbalance, etc. Focal infections appear to produce much more marked nervous symptoms and to produce them with greater frequency in individuals with arterial hypotension than in those with normal blood pressure or an arterial hypertension. This is probably an endocrine reaction.

ABSTRACT OF DISCUSSION

Dr. George M. Dorrance, Philadelphia: It has been our practice, when we are not sure that a patient has a chronic infection of the antrum, not to trust to the nasal packing but to "take a look." In one case, which Dr. McCarthy will remember, the tonsils had been removed and the teeth were taken care of. Surely, there was nothing wrong with that antrum. Until the focal infection was removed, however, the patient did not improve. As soon as the antrum was drained, the patient immediately improved and was able to work. We have had similar experiences in three cases. One should always consider the possibility of a chronically infected antrum; if one is not sure of it, it does not do any harm to open into it. We find that practically all these patients have a dull ache over the antrum. On the question of tonsils, I agree with Dr. McCarthy. There is no doubt that chronic infection reacts largely through the liver and the kidney. There is a question at present whether one should tap the abscess at the periapical area. It is not worth while doing that when there is a psychosis. One should take the teeth out and should not try to drain the abscess.

Dr. William A. Jaquette, Philadelphia: I believe we cannot disagree in any instance when it is absolutely necessary to remove all possible dental foci of infection in one manner or another. Dr. McCarthy has been a little severe on members of my profession in their delinquencies, but I am sure that he has been justified in many instances. He is giving the subject attention from the highest point of view, and there are many members of my profession who are giving it the same type of serious consideration. If the dentist would give this subject sincere and scientific study, he would not disagree in the removal of those dental foci. Determination of extraction of teeth should not be in the hands of a physician but in the hands of a dentist. There is a tendency among physicians to extract all teeth with crowns and to leave next to that crown a tooth with a small filling in it. That tooth, however, may be more certainly infected than the one with the crown. Many dentists are putting crowns on vital teeth. It is not the crown that is the deciding point in the extraction of teeth. Most serious dentists believe that in critical cases, such as those outlined by Dr. McCarthy, all teeth that are even devitalized, even though there is no roentgen-ray evidence, should be removed. Dr. Dorrance said that with those teeth one should not even attempt the amputation of the root end. With that I concur.

Dr. Dudley E. Mackey, Bloomfield, N. J.: I have observed in the last two years more thant 3,000 cases treated through our dental department. A roentgenogram, when indicated, is made of every patient entering the Essex County Hospital for the Insane; the patient is then treated by the dentist or physician. We found that about 64 per cent. had visceroptosis; 68 per cent. showed dental defects, either one or a number of teeth being infected. About 27 per cent. showed pathologic tonsils. I do not remember the percentage of thyroids, but 17 per cent. were tuberculous, and 70 per cent. had sinuses showing abnormal conditions, with antrum and ethmoid infection predominating. In the last two months we have started a general examination of every male patient to determine the condition of the sinuses. Up to this time I have completed 100 cases. Seventy per cent. so far show abnormal conditions. Most of the cases show infection of the antrum, and a large percentage of them showed infected ethmoids. We have not had the same experience as Dr. Cotton in the removal of kinks of the colon, nor have we had the excellent results he has reported in the removal of teeth, but we have helped the patients physically by the removal of teeth and by the treatment of their physical conditions. We have not been able to determine whether the mental condition is due to dental or gastro-intestinal disturbance, yet we find that improving the physical deficiencies tends to improve some patients mentally, while in others there is no change.

Dr. James R. Cameron, Philadelphia: One of the big points that appealed to me was the plea for cooperation between the neurologist or the internist and the dentist. However, Dr. McCarthy must not overlook the fact that so often patients are referred to the dentist from the internist or the neurologist with a request that the teeth be extracted; there is no history of the case. If the neurologist or internist would send some kind of a history along with the patient, the dentist would appreciate what is wanted and would be willing to cooperate to the fullest extent. In hospital practice, when the dental surgeon is called into consultation, he has access to the entire medical history of the patient; he knows what the internist wants and he tries to cooperate, whereas in private practice the patient is often sent from the neurologist to the dentist, from the dentist to the extraction specialist, and the extraction specialist knows nothing about the history of the case. Closer cooperation and exchange of ideas is most essential.

Dr. Carl W. Waldron, Minneapolis: In cases in which there is a psychosis or any nervous or mental condition, it is the duty of the nervous and mental disease specialist in charge to get in touch with the dentist and talk the case over with him to assure full coopertaion. Many patients are simply sent to the dental practitioner to have their mouths looked over and put in good condition. That does not further cooperation. It is the duty of the rhinologist who finds dental infection beneath an infected sinus to get in touch with the dentist and be assured of the technic that will be carried out in taking care of that dental infection. I have wondered, after listening to Dr. McCarthy's opinions in regard to the taking care of periapical areas, whether in his locality an accurate check has been made of the various methods of handling dental infection. In the Middle West we feel that careful exposure of the parts by a modified alveolar resection, with the enucleation method of removing infection, gives much less reaction than the old-fashioned simple extraction. It has been checked up with the temperature reaction, the effect on the blood counts, and the effect on the patient's feeling and general condition. Many oral surgeons feel that it is safer to undertake careful open view surgery of the alveolar area than simple extraction and drainage. This has been my reaction, because I have yet to see any untoward results from proper oral surgical procedures. Rather than injudicious curettage, I suggest that open view operations be carried out, because they do not menace the patient from the standpoint of the spreading of streptococcic infection.

Dr. D. J. McCarthy, Philadelphia: I limited myself to the condition about the teeth. When the question of sinus involvement is considered, I agree with Dr. Mackey. We keep in mind focal infections in the teeth, and I look for focal infections all over the body. Dr. Mackey said he found visceroptosis in 64 per cent. of the cases. That is exactly in line with the subject of my paper. I do not agree with any clinician who says that a man is born with a Botticelli figure, with the liver down and with the stomach and colon in the pelvis. I think such a child was born normal, and some infection in early childhood reduced the vitality of the growing form; when the crawling quadruped got on its feet, it was so relaxed that its organs dropped down. Visceroptosis cases are manifestations of some severe infection in early childhood that give rise to a disturbance and stress on the endocrine system. When the child comes to adolescence, and added focal infection develops, a psychosis is often precipitated. I have no quarrel with Dr. Jaquette. I did not in the slightest degree intend to reflect on the dental profession any more than on the medical profession, but I can show you films of work done by dentists that the dental profession would be ashamed of. The same thing is true of the diagnoses of the patients that come through from physicians who have bungled their work. It is not my policy to criticize, but when I see case after case of bridge work covering old infected stumps, I know that something is wrong. Very often I study the case again, and if the dentist has not done what I consider necessary, I take the patient out of his hands and put him in the hands of a dentist who will do good and complete work. Does the dentist ever say, "Tell me about your health. What diseases have you had? Have you had any attacks of tonsillitis or rheumatism? Have you had any heart disease?" Every time that I go to a dentist he sticks a mirror in my mouth, grubs around, makes a note or two, and then reaches for a drill. The dentist who will not take the history of the case is in the same position as the practitioner who prescribes for the patient without getting his history. I quite agree that in every case of importance there should be cooperation between the dentist and the physician.

CARBON DIOXID AS AN AID IN GENERAL ANESTHESIA*

JOHN S LUNDY, M D
ROCHESTER, MINN.

The introduction of ethylene into the field of anesthesia in the early part of 1923 by Luckhardt[1] suggested the need for an enlarged gas machine by which ethylene, nitrous oxid, oxygen, carbon dioxid and ether could be administered[2] The work of Henderson, Haggard and Coburn[3] and White,[4] showing that carbon dioxid aids in the introduction of ether[5] as well as in its elimination, and that it is also an aid in ethylene anesthesia,[6] prompted me to include a control for carbon dioxid, thus making an apparatus of the four-control type. Some of these machines were the Gwathmey type; others were the Heidbrink type. Attachments for the ordinary gas machine were not satisfactory.

In the cases discussed here, in which the apparatus was used, carbon dioxid was shown to be an aid in gas and in gas-ether anesthesia. The tabulation of cases shows the various combinations in which carbon dioxid was used from July, 1924, to September, 1925, in the Mayo Clinic This series of cases covers almost the entire field of general surgery

Administration of Carbon Dioxid

	1924	1925
Carbon dioxid and oxygen (to resuscitate infants)	4	20
Local, carbon dioxid and oxygen	..	1
Carbon dioxid and oxygen after ether		1
Nitrous oxid, carbon dioxid and oxygen		91
Nitrous oxid, ethylene, carbon dioxid and oxygen	13	438
Nitrous oxid, carbon dioxid, oxygen and ether		17
Nitrous oxid, ethylene, carbon dioxid, oxygen and ether	9	245
Ethylene, carbon dioxid	29	67
Ethylene, carbon dioxid,		269
Local, nitrous oxid, car	2	1
Local, ethylene, carbon	..	43
Local, nitrous oxid, ethy	1	33
Local, ethylene, carbon dioxid, oxygen and ether		38
Local, nitrous oxid, ethylene, carbon dioxid, oxygen and ether		28
Total	58	1,292

The percentages recorded are only approximate, and are calculated from the flow of the various gases through the machine A patient, of course, cannot tolerate more than between 4 and 6 per cent of carbon dioxid in the mixture for continuous inhalation I have been guided in the amount by the character of the respiration, and have endeavored not to exceed an amount sufficient approximately to double the depth of respiration. In most cases, respiration was increased in depth more than in rate, according to the well recognized physiologic effects of carbon dioxid. Individual tanks of nitrous oxid, ethylene, oxygen and carbon dioxid have been used. Carbon dioxid has been used both intermittently and continuously in the induction, maintenance and termination of various anesthesias, or whenever the anesthetist wished to control the patient's respirations.

TECHNIC

For the first or induction period, the breathing bag is filled with a mixture of nitrous oxid, about 80 per cent., and oxygen, 20 per cent. The anesthetist smells the mixture to be sure that there is no unpleasant odor due to stale gas or escaping ethylene, ether or carbon dioxid. The mask is then placed over the patient's face and he breathes into and out of the bag. After from four to six breaths, the carbon dioxid is gradually added to the mixture, a flow of one or two holes on the Gwathmey machine and a flow of from 3 to 10 gallons an hour in the new Heidbrink machine being used The breathing bag is 35 cm in diameter, and the carbon dioxid flows about one and a half minutes to obtain the desired effect on respiration. Ethylene is then gradually added, and the nitrous oxid gradually shut off until the mixture is approximately 75 per cent. ethylene, 20 per cent. oxygen, and 5 per cent. carbon dioxid On a Gwathmey machine, the sight feed flow is four or five holes of ethylene, two or three of oxygen and one or two of carbon dioxid The four to six breaths of nitrous oxid and oxygen produce slight vertigo and dull the patient's sense of smell, so that the gradual addition of the ethylene is, as a rule, not unpleasant The carbon dioxid stimulates the patient to breathe deeply of the mixture and smooths out the second stage of anesthesia Four or five breaths of the mixture containing ethylene, as a rule, suffice to render the patient unconscious and produce light anesthesia, which rapidly becomes deeper until the third stage is established. Apparently the increase in the depth of respiration makes the anesthesia smoother and keeps the patient pinker than when carbon dioxid is not used This is equally true whether or not a preliminary hypnotic of morphin has been employed

In order to produce satisfactory relaxation, it is often necessary to add ether to the ethylene Carbon dioxid has speeded up the absorption of ether and has almost entirely eliminated respiratory inhibition The use of carbon dioxid, as a rule, reduced the quantity of ether used by about one half, the vapor was equally reduced in concentration, probably because of an increase in absorption and a decrease in waste. If carbon dioxid has not been used the patient may strain and hold his breath when the peritoneum is being incised and the exploring hand passed through the abdomen. For certain patients it is necessary to increase the percentage of carbon dioxid in the mixture at the time of the exploration Strong concentrations, however, must be avoided With the Gwathmey type of machine in such cases, not more than three holes of carbon dioxid are used, and with the Heidbrink type, not more than 10 or 12 gallons an hour. The increased flow of carbon dioxid, although considerable, lasts for only a minute or two, and increases the percentage inspired but slightly. When a diseased organ has been delivered into the wound, the carbon dioxid and ether are still further decreased The machine will then be feeding approximately 75 per cent. ethylene, 20 per cent oxygen and from 3 to 5 per cent carbon dioxid, besides, of course, the slight amount of carbon dioxid supplied by rebreathing.

From time to time the anesthetist should open the exhaling valve and smell of the mixture in the bag.

The odor of ether in the bag should never be stronger than the anesthetist himself can tolerate, and the carbon dioxid should never be discernible. During the operative work on viscera at rest, the anesthetic mixture usually consists of ethylene and oxygen with small quantities of carbon dioxid. Before the viscera are replaced within the abdominal cavity and the abdominal wall is closed, ether may be added and the percentage of carbon dioxid raised, so that the machine shows a flow of from 5 to 7 gallons an hour (from 3 to 7 per cent.) of the total flow. If the abdominal wall has been blocked regionally with procain as part of the preoperative preparation, ether will probably not be necessary for the closure. It is not desirable to administer carbon dioxid in quantities sufficient to cause overvigorous movements of the chest and the abdomen at any time. When the patient's normal respirations have been approximately doubled in depth, the right amount of carbon dioxid is being used, and the ether may be added. After the peritoneum has been closed, nitrous oxid may be substituted for the ethylene and ether. The exhaling valve should then be opened and from 3 to 5 per cent. of carbon dioxid used. The ethylene and ether are thus gradually eliminated and replaced by nitrous oxid, and by the time the skin sutures have been placed a large amount of ether and ethylene will have been eliminated. As a rule, patients awaken a short time after the mask has been lifted from the face. Some of them vomit, but not excessively as a rule. In operations on the gallbladder, the grunt occasioned by the surgeon's pull on the organ is less noticeable when carbon dioxid is used, and sometimes it is entirely absent. In extra-abdominal operations it is often unnecessary to add ether to the gas, when carbon dioxid is used.

CARBON DIOXID IN OBSTETRICS

Carbon dioxid has proved of value for obstetric anesthesia. A mixture of nitrous oxid, about 50 per cent., and oxygen, 50 per cent., is given in the early period of pain, and when the pains become more severe the nitrous oxid is gradually increased until the mixture in the bag is from about 80 to 85 per cent. nitrous oxid and from 15 to 20 per cent. oxygen. When the pains become still more severe, ethylene is added and the nitrous oxid reduced, about 40 per cent. of nitrous oxid, 40 per cent. of ethylene, and 20 per cent. of oxygen being used. This mixture is gradually changed as the pains increase until the nitrous oxid is discontinued and the bag is filled with ethylene, about 80 per cent., and oxygen, 20 per cent. As soon as the patient gives the sign of an approaching pain, she is given four or five breaths of the mixture in the bag. Because of the intermittent administration of a few breaths at a time, some patients will require as much as 90 per cent. of ethylene and 10 per cent. of oxygen. As the baby's head presses against the perineum and begins to dilate the external outlet, some patients hold their breath and bear down in spite of all remonstrances; carbon dioxid may then be of advantage. Anesthesia is often quickly induced, and the mother prevented from holding her breath and bearing down. It is obviously not always possible to get this effect in an intermittent anesthesia.

RESUSCITATING THE NEW-BORN INFANT

If the new-born infant does not breathe well, respiration may be established quickly by the use of artificial respiration and oxygen containing 5 per cent. of carbon dioxid. The obstetrician places his hands so that his palms are against the baby's chest, the fingers point toward the head, and the baby's arms protrude between his thumb and index finger. He gently presses on the infant's chest with his thumbs. The anesthetist stands at the baby's head and places the mask snugly over its mouth and nose. As the obstetrician's thumbs rise, the oxygen and carbon dioxid are administered under slightly increased pressure so that they inflate the baby's lungs. This manipulation is, as a rule, sufficient to start respiration after it has been repeated a few times, if the air passages are clear. As the pulmonary tissue is very delicate, great caution must be used not to have the pressure exceed 3 cm. of water; this can be controlled by inserting a water safety valve.

DENTAL ANESTHESIA

In dental surgery, carbon dioxid aids in maintaining nitrous oxid or ethylene anesthesia with little struggling or cyanosis. This has been of decided advantage in dental operations on children.[3]

ADVANTAGES OF CARBON DIOXID

The advantages of using carbon dioxid during the induction and maintenance and at the termination of anesthesia are:

1. An increase in the rate of absorption of ether, when it is used alone or with other anesthetic agents, by increasing the volume of respiration.[5]
2. Low concentrations of ether vapor.
3. Reduction of struggling, breath holding and shallow breathing, and the absence of cyanosis.
4. Greater relaxation in light anesthesia.
5. The quieting effect of morphin, without its occasional bad effect on the respiratory center.
6. The starting of respiration in the new-born infant without the usual vigorous manipulations, if the air passages are clear.
7. Better prognosis if patients are moribund from operative procedures or for other reasons.
8. A lack of idiosyncrasies to low concentrations (3 per cent.).
9. Safer induction and maintenance of gas anesthesia in children.
10. The hastening of the elimination of ether and revival of the patient.[4]

INDICATIONS OF OVERDOSE

Carbon dioxid has been used in the present series of cases during induction and maintenance and at the termination of anesthesia in nearly all types of surgery. When used in moderation, it has been of assistance to the anesthetist. It is distinctly a disadvantage, however, to use it in strong concentrations. The signs of overdosage are coughing, breath holding and overvigorous abdominal and chest movements. One piece of apparatus is so constructed that it limits the quantity of carbon dioxid, but this does not make it fool-proof. It is of the utmost importance to caution the anesthetist never to use carbon dioxid *in strong concentrations.*

COMMENT

On several occasions, I have administered oxygen to normal persons, and have asked them to hold their breath voluntarily at intervals. I then gradually added carbon dioxid to the oxygen until they were unable to hold their breath. From these experiments it would seem that with loss of consciousness, a patient could be made to breathe under all circumstances by administering carbon dioxid in moderate quantities. However, the throat and laryngeal reflexes usually operate regardless of the effect of carbon dioxid on the respiratory center. This protective mechanism is most noticeable with light anesthesia. The throat and laryngeal reflexes also seem to protect the patient against the inhalation of great concentrations of ether or carbon dioxid, which would, of course, be deleterious. Nevertheless, every care must be used to keep the air passages patent and free from foreign bodies and fluids.

The work of Haggard, on dogs, wherein he laid the foundation for the use of carbon dioxid with ether, should be carefully read by all who are interested in this subject. Haggard has shown that the increase in the volume of respiration caused by the inhalation of carbon dioxid hastens the absorption of ether vapor, and that anesthesia is as quickly produced when carbon dioxid is used with a low concentration of ether vapor as when a highly concentrated ether vapor is used alone. Theoretically, then, the addition of carbon dioxid would probably reduce the frequency of postoperative pneumonia, because a more dilute vapor could be used with consequent less irritation of the air passages.

PREFERENCE FOR CARBON DIOXID

The patients in this series have been anesthetized by about ten different anesthetists; all are enthusiastic in advocating the use of carbon dioxid as a means of making general anesthesia easier to induce and maintain, and are reluctant to administer an anesthetic without having carbon dioxid at hand. It is generally agreed, among those who have administered the anesthetics in this series, that when ether and carbon dioxid are added in proper amounts, either singly or together, to nitrous oxid or ethylene, the resulting anesthesia is usually satisfactory.

INVESTIGATION OF THE ACTION OF CARBON DIOXID IN GAS ANESTHESIA

Future investigation may explain how carbon dioxid assists in producing relaxation, if it actually does produce it. In certain cases, when it is used during light anesthesia, the fighting of the excitement stage is lessened or eliminated. Possibly, control of the respiratory center or breathing reflex causes struggling to disappear to some extent. Sometimes the effect of carbon dioxid during anesthesia is similar to that produced during bimanual examination when the patient is asked to breathe deeply through the mouth; under those circumstances not much relaxation is produced, but much of the tenseness is abolished. In some anesthesias it seems that carbon dioxid, by producing deep breathing, has coordinated the reflexes to such an extent that the nervous, tense patient becomes as quiet as in normal sleep. In normal sleep one is usually somewhat relaxed, yet moves and turns from time to time. It might be said that carbon dioxid, when it is functioning as desired, brings an otherwise tense patient to the relaxation of sleep, and that the anesthetic agents carry the patient on into a state of complete relaxation. Carbon dioxid, when used in proper amounts with anesthetic agents, seems to contribute definitely to the relaxation. The explanation as herein set forth is based on observation and deduction and may be erroneous; nevertheless, we have obtained good results from the use of carbon dioxid during gas anesthesia. I have frequently observed that when using carbon dioxid in gas anesthesia, even without ether, the movements, especially of the extremities, are less frequent. Some patients who are so lightly anesthetized that they will open and close their eyes when given carbon dioxid often make no other movement, even when the incision is made.

CONCLUSIONS

1. Carbon dioxid in moderate concentration assists in producing anesthesia, rendering the anesthetic apparently safer and easier to administer.
2. Carbon dioxid should be used in such concentrations as will produce optimal results, and these vary with the individual and the type and stage of the operation. Too much carbon dioxid is worse than none, and care should be exercised to prevent more than 5 per cent. being used.
3. The results thus far in a series of 1,350 cases in the Mayo Clinic are satisfactory enough to warrant further investigation by others in the use of carbon dioxid during the induction and maintenance and at the termination of ordinary general anesthesia.

HEMATOMA OCCURRING SPONTANEOUSLY IN SHEATH OF RECTUS ABDOMINIS MUSCLE

A CONSIDERATION OF ITS GYNECOLOGIC AND OBSTETRIC SIGNIFICANCE: REPORT OF TWO CASES

CAREY CULBERTSON, M.D.
CHICAGO

Rupture of the fibers of the rectus abdominis muscle, when not due to external violence, occurs as the result of strong or unusual contraction, though in a few cases there is a record of nothing more than ordinary muscular effort. As a rule this accident carries with it laceration of the branches of the epigastric vessels, sometimes of the trunks themselves, and, as a result, a hematoma forms within the aponeurotic sheath. This condition is of surgical interest not only because it constitutes a lesion, but also because the signs and symptoms produced lead to misinterpretation in suggesting intraperitoneal disease. When the accident occurs in women, it is nearly always mistaken for some critical form of abdominal or pelvic pathologic condition. Surgical textbooks either omit the subject or refer to it briefly, and gynecologic textbooks make no reference to it. Haubold[1] refers to subcutaneous lacerations of the musculature of the abdominal wall as not rare. He states that the lesion is most likely to happen in acrobats and has occurred in persons convalescing from prolonged infectious diseases, such as typhoid fever, as a result of slight exertion. The earliest reference to the condition is that of Maydl[2] in 1882; the first American report, that of Pilcher[3] in 1913.

In 1923, Wohlgemuth[4] collected 127 cases from the literature, 107 of which had occurred in young men, chiefly turners, soldiers and cavalrymen. He considered these as not strictly spontaneous ruptures, regarding extreme muscular effort as traumatic in nature; real spontaneous rupture occurred in the remaining twenty cases, seven in elderly persons and the rest in those suffering from infectious diseases, burns, chilling and the like, or during pregnancy and labor.

Commenting on the myalgia and muscular weakness so common in influenza, Cooper Cole[5] found abscess formation in some muscles, and marked degeneration was repeatedly noted in the rectus abdominis. The muscles looked gray and cooked, and flaked readily a few hours after death. Their fibers were found to be ruptured, as cleanly as if cut. Hemorrhages were frequent, usually in the lowest quarter only, occasionally throughout the length of the sheath. Klotz[6] found the same condition and regarded it as primarily a focal degeneration. He found similar foci in the pectoral, psoas, gluteus and sternomastoid muscles and suggested that this may explain certain postinfluenzal deep seated abscesses. Rost[7] has reported two cases occurring in the course of typhoid fever; Carnot[8] discussed those complicating diseases of the liver.

Other factors appearing in case reports are coughing, vomiting, straining at stool and tetanic convulsions. According to Perman,[9] the accident results from more or less violent muscular effort, abnormally strong or prolonged contraction of the rectus when riding, exercising or lifting, and in efforts to maintain balance when falling. It becomes evident from a study of the cases that rectus rupture takes place more often in amateurs taking part in athletic exercises or in military recruits, rather than in well trained and muscularly hardened athletes or soldiers. Thus, Perman cites numerous cases, reported by various writers, in which abdominal wall hematomas occurred in cavalrymen in their early training, the accident resulting from trying to maintain balance without stirrups, vaulting into the saddle from the ground, and like exercises.

As regards the cases occurring in women, of the fourteen in Perman's series, all but one were over 35 years of age, and most of them were multiparas. Rectus hematoma appears most frequently among the middle aged and elderly, and the exertion, as a rule, is much less than that required to produce it in men. Perman suggests that this is due to the fact that woman's musculature is not as strong as man's, and that the rectus becomes still further weakened by the distention of repeated pregnancies. The loss of elasticity with advancing years may be offered as another factor, and changes in the walls of the blood vessels as a third.

Hilgenreiner[10] has offered a classification of two groups: the first, traumatic, due to (*a*) direct or (*b*) indirect force, occurring chiefly in young men of sound muscles; the second, spontaneous, occurring when the muscles are weakened or atrophic, (*a*) in infections, (*b*) in pregnancy, labor or the puerperium, and (*c*) in elderly women.

As a rule, the hematoma occurs between the umbilicus and symphysis pubis, but in a few cases it has been found above the navel. It is nearly always unilateral, seven of Perman's cases involving the right rectus, five the left and one being bilateral. Of Wohlgemuth's series, forty-five were right, thirty-three left, and four bilateral. Seventy-nine were below the umbilicus and five above. The amount of blood involved varies greatly, and the symptoms produced vary proportionately in severity. A chief characteristic feature appears to be the occurrence of pain, with or without previous muscular effort, slight at first but continuous, or increasing; then, with continued activity, a sudden, sharp attack of pain, increasing even after the patient has been forced to go to bed.

A second characteristic is the suggestion of peritonitis, which accounts for the mistaken diagnosis, so frequently made, of intra-abdominal disease. Quénu has called attention to this, in reporting cases due to external violence, as "peritoneal symptoms in nonpenetrating wounds of the abdomen." As Hartmann[11] states, the symptoms of peritonitis may result from an irritation of the external surface of the peritoneum, without there being in reality the least inflammatory reaction involving the serous membrane. The same may be said also for the symptoms of pelvic hematocele. Hence, the pain and general reaction resulting from rectus sheath hematoma suggests a more serious situation than actually exists.

Differential diagnosis is rendered difficult by the added fact that there is no history of trauma and that only too often statements by the patient regarding lifting, straining, coughing, falling and the like are disregarded. Patients often ascribe illness due to intra-abdominal disease to the same apparently unimportant features.

In 1916, Andrews[12] reported three cases of rectus hematoma, in one of which the patient was pregnant. Hartmann's report of one case appeared in 1917, Emerson's[13] in 1918, Schumann's[14] in 1919 and Behan's[15] in 1920. Of these, Schumann's patient was also pregnant at the time the injury occurred. A recent comprehensive survey of the subject was that of Perman, appearing in 1922. This report cited only Behan's of the foregoing cases, and included fourteen others occurring in women, seven of which were ascribed, respectively, to Kotzaroff, Heintze, Lambrethsen, Bauereisen, Bird, Wiener and Lehman. In 1923 a case was described by Hilgenreiner and one by Wohlgemuth, the latter adding to his own two others attributed to Ehrenfest and Koerte. In the following year four cases were reported, one each by Harris,[16] Blond,[17] von Renner[18] and Whittingdale.[19] This comprises a total of twenty-seven cases of rectus hematoma occurring in women not pregnant.

A consideration of such cases as have occurred in women shows that rectus hematoma bears a strong resemblance, symptomatically, to intraperitoneal or pelvic disease. A brief summary[20] of these cases brings out the points important in differential diagnosis.

The case coming under my observation, which has called forth this report, is as follows:

A well developed woman, aged 34, of normal weight, 125 pounds (56.7 kg.), the mother of two children, 10 and 5 years old, respectively, was accustomed to an active home and outdoor life. She gave a history of no previous illness except diphtheria eleven years previously. June 11, 1923, while driving from the tee in a game of golf, she experienced a sudden, sharp pain in the lower right abdomen. This persisted, but she finished the first nine holes, refusing to play a second round because of the pain. She did not play golf again until five days later, June 16. During the first seven holes she noticed some pain in her right side, and this was much more severe when she got a long drive with the wooden clubs. When she drove from the eighth tee she "suffered a terribly sharp pain, as if some one were cutting the right side open with a knife." The eighth and ninth holes were finished, but under great pain. While taking her shower after the game she noticed a swelling in the right side and, because of this and the pain, she sent for her physician. He was unable to attend her at once, and she went to a formal tea, where she "did nothing but try to protect her injured side from the crowd." That evening she attended a dinner party, later driving 25 miles by motor car to her home, where she arrived in partial collapse. The next day she remained in bed under the influence of stimulants and sedatives.

During the five days between the two games of golf the patient suffered chills on two different nights. Once during that week she went swimming and was able to dive three or four times without noticing pain. She entered the hospital, June 18, seven days after her first attack of pain and two days following the second attack, under the diagnosis of strangulated ovarian cyst, or tubal pregnancy. In this connection it should be stated that her menstruation had been regular, occurring every twenty-eight days, of from five to six days' duration, the last two periods having occurred, April 24 and May 25, respectively.

On examination the abdomen was flat, firm, soft and elastic, except for a somewhat indefinite mass or resistant area just above Poupart's ligament on the right side. This area was tender and painful. Vaginally, the uterus lay in retroversion, and was normal in size and freely movable. The left appendage was prolapsed, but on the right side a fixed, tender mass the size of an orange was palpable. The most notable thing about this mass was that it appeared to lie in the anterior pelvis, as if anterior to the round ligament, or, as described in the case record, behind Poupart's ligament.

The patient experienced no chills while under observation; her temperature ranged from 99.5 to 100.2 F., and the leukocyte count was 12,000. After two days' observation, an operation was performed. The skin of the abdominal wall showed no discoloration, but as soon as the subcutaneous fat was reached, an extensive ecchymosis was evident, involving the fat, aponeurosis and right rectus muscle. The structures were not only discolored but also infiltrated and swollen, and between the lower portion of the muscle and its deep fascial sheath lay several ounces of clotted blood. This was removed and revealed the muscle fibers, not divided sharply but as if shredded, and there was some separation of the muscle bundles longitudinally. This area, as it involved the muscle, extended from the symphysis for 10 cm. upward. There was no active bleeding. The ecchymosis involved the peritoneum, which, though markedly discolored, was smooth and shiny on its inner surface, and extended farther into the right round and broad ligaments. This discoloration was apparent throughout the right pelvic wall as far down as the uterosacral ligament, but stopped short of the tube, ovary and uterus by a sharp line of demarcation. The uterus and its appendages were normal.

Since the preparation of this report I have been permitted by Dr. Carl Beck to include one more case:

An Italian woman, obese, about 40 years of age, who had had six children, was suffering from a severe bronchitis. She had coughed hard for several days, when she began to experience pain in the upper right quadrant of the abdomen. Examination showed a hard, tender swelling, the size of a hen's egg. Vomiting, jaundice and constipation were absent. A diagnosis of gallbladder disease was made. An operation revealed that the mass was a hematoma in the sheath of the rectus muscle, just beneath the free edge of the ribs. There was some laceration of muscle fibers but no active bleeding. The peritoneum was not opened.

The obstetric significance of rectus hematoma is interesting. That it occurs rarely is evident, since there are but ten cases in Wohlgemuth's series. At first thought this is surprising, in view of the fact that in pregnancy the recti are more or less under tension and often diastatic. On the other hand, the patients are in the first half of life, before the tissues have become less elastic. The immediate causes, in most cases, are the same as those appearing in the nonpregnant. In Stoeckel's two cases the hemorrhage was occasioned by coughing. One patient was a quartipara in the sixth month of gestation; the other, a sextipara at term, labor not having begun.

Toft's patient, a tertipara, was 30 years old and pregnant six months. She had had bronchitis for several weeks and coughed freely at times. For three weeks there had been pain in the right lower abdomen. This suddenly became severe, and a resistant area developed to the right of the enlarged uterus. The next day there were anemia and signs of ileus. Rupture of the pregnant uterus was feared. At operation a cavity seven inches (213 cm.) long was exposed, filled with blood coagula, in the rectus sheath. The mass had ruptured intraperitoneally, with much free blood in the abdominal cavity. This is the only case reported in which the hematoma had broken through the serous coat.

The patient whose case Sjoblom reported was at the end of her pregnancy, and the accident of rupture was ascribed to no definite cause. In Mace's case the hematoma developed during pregnancy. Vogt's patient was a secundipara, 21 years of age. The hematoma was bilateral, and was discovered after spontaneous labor and ascribed to it. Lichtenstein reported a case in which, after normal labor, the rupture was discovered, correctly diagnosed and treated conservatively. The patient was a primipara, 32 years of age.

Schumann's patient, on the contrary, was a septipara, 44 years of age and obese. Strictly speaking this was not a case of spontaneous development but, because of its interesting diagnostic features, is added to the series. During the last pregnancy she sustained an injury, striking the edge of an open door heavily with the right side of the abdomen. Severe pain and disability followed, but the symptoms disappeared within a few days. Occasional attacks of pain in the right side persisted, and after labor a distinct mass was evident in the right lower quadrant. Within three months ascites developed, with dyspnea and edema of the legs. For the ascites, tapping had been done six times. A large tender mass was palpable in the right iliac fossa, but vaginal examination revealed no deep pelvic abnormalities. A provisional diagnosis was made of some rapidly growing form of generalized malignancy. After the ascitic fluid had been drained from the abdomen, no intraperitoneal disease was found. Within the substance of the rectus muscle lay a huge, old hematoma, after the removal of which the torn end of the deep epigastric artery was found. In this case the injury was due to external violence and occurred during pregnancy, but marked symptoms did not develop until after labor. It is the only case in which ascites occurred.

Andrews' report includes three cases, the second and third of which have been noted.[20] His first case was that of a woman, aged 30, who had been well previously except for acute rheumatism in adolescence. The illness occasioning the chiefly turners, soldiers and cavalrymen. He considered these as not strictly spontaneous ruptures, regarding extreme muscular effort as traumatic in nature; real spontaneous rupture occurred in the remaining twenty cases, seven in elderly persons and the rest in those suffering from infectious diseases, burns, chilling and the like, or during pregnancy and labor.

---

[20] Brief abstracts of the twenty-seven cases heretofore described appear in the complete paper as published in the proceedings of the American Gynecological Society, 1925.

Commenting on the myalgia and muscular weakness so common in influenza, Cooper Cole[5] found abscess formation in some muscles, and marked degeneration was repeatedly noted in the rectus abdominis. The muscles looked gray and cooked, and flaked readily a few hours after death. Their fibers were found to be ruptured, as cleanly as if cut. Hemorrhages were frequent, usually in the lowest quarter only, occasionally throughout the length of the sheath. Klotz[6] found the same condition and regarded it as primarily a focal degeneration. He found similar foci in the pectoral, psoas, gluteus and sternomastoid muscles and suggested that this may explain certain postinfluenzal deep seated abscesses. Rost[7] has reported two cases occurring in the course of typhoid fever; Carnot[8] discussed those complicating diseases of the liver.

Other factors appearing in case reports are coughing, vomiting, straining at stool and tetanic convulsions. According to Perman,[9] the accident results from more or less violent muscular effort, abnormally strong or prolonged contraction of the rectus when riding, exercising or lifting, and in efforts to maintain balance when falling. It becomes evident from a study of the cases that rectus rupture takes place more often in amateurs taking part in athletic exercises or in military recruits, rather than in well trained and muscularly hardened athletes or soldiers. Thus, Perman cites numerous cases, reported by various writers, in which abdominal wall hematomas occurred in cavalrymen in their early training, the accident resulting from trying to maintain balance without stirrups, vaulting into the saddle from the ground, and like exercises.

As regards the cases occurring in women, of the fourteen in Perman's series, all but one were over 35 years of age, and most of them were multiparas. Rectus hematoma appears most frequently among the middle aged and elderly, and the exertion, as a rule, is much less than that required to produce it in men. Perman suggests that this is due to the fact that woman's musculature is not as strong as man's, and that the rectus becomes still further weakened by the distention of repeated pregnancies. The loss of elasticity with advancing years may be offered as another factor, and changes in the walls of the blood vessels as a third.

Hilgenreiner[10] has offered a classification of two groups: the first, traumatic, due to (*a*) direct or (*b*) indirect force, occurring chiefly in young men of sound muscles; the second, spontaneous, occurring when the muscles are weakened or atrophic, (*a*) in infections, (*b*) in pregnancy, labor or the puerperium, and (*c*) in elderly women.

As a rule, the hematoma occurs between the umbilicus and symphysis pubis, but in a few cases it has been found above the navel. It is nearly always unilateral, seven of Perman's cases involving the right rectus, five the left and one being bilateral. Of Wohlgemuth's series, forty-five were right, thirty-three left, and four bilateral. Seventy-nine were below the umbilicus and five above. The amount of blood involved varies greatly, and the symptoms produced vary proportionately in severity. A chief characteristic feature appears to be the occurrence of pain, with or without previous muscular effort, slight at first but continuous, or increasing; then, with continued activity, a sudden, sharp attack of pain, increasing even after the patient has been forced to go to bed.

A second characteristic is the suggestion of peritonitis, which accounts for the mistaken diagnosis, so frequently made, of intra-abdominal disease. Quénu has called attention to this, in reporting cases due to external violence, as "peritoneal symptoms in nonpenetrating wounds of the abdomen." As Hartmann[11] states, the symptoms of peritonitis may result from an irritation of the external surface of the peritoneum, without there being in reality the least inflammatory reaction involving the serous membrane. The same may be said also for the symptoms of pelvic hematocele. Hence, the pain and general reaction resulting from rectus sheath hematoma suggests a more serious situation than actually exists.

Differential diagnosis is rendered difficult by the added fact that there is no history of trauma and that only too often statements by the patient regarding lifting, straining, coughing, falling and the like are disregarded. Patients often ascribe illness due to intra-abdominal disease to the same apparently unimportant features.

In 1916, Andrews[12] reported three cases of rectus hematoma, in one of which the patient was pregnant. Hartmann's report of one case appeared in 1917, Emerson's[13] in 1918, Schumann's[14] in 1919 and Behan's[15] in 1920. Of these, Schumann's patient was also pregnant at the time the injury occurred. A recent comprehensive survey of the subject was that of Perman, appearing in 1922. This report cited only Behan's of the foregoing cases, and included fourteen others occurring in women, seven of which were ascribed, respectively, to Kotzaroff, Heintze, Lambrethsen, Bauereisen, Bird, Wiener and Lehman. In 1923 a case was described by Hilgenreiner and one by Wohlgemuth, the latter adding to his own two others attributed to Ehrenfest and Koerte. In the following year four cases were reported, one each by Harris,[16] Blond,[17] von Renner[18] and Whittingdale.[19] This comprises a total of twenty-seven cases of rectus hematoma occurring in women not pregnant.

A consideration of such cases as have occurred in women shows that rectus hematoma bears a strong resemblance, symptomatically, to intraperitoneal or pelvic disease. A brief summary [20] of these cases brings out the points important in differential diagnosis.

The case coming under my observation, which has called forth this report, is as follows:

A well developed woman, aged 34, of normal weight, 125 pounds (56.7 kg.), the mother of two children, 10 and 5 years old, respectively, was accustomed to an active home and outdoor life. She gave a history of no previous illness except diphtheria eleven years previously. June 11, 1923, while driving from the tee in a game of golf, she experienced a sudden, sharp pain in the lower right abdomen. This persisted, but she finished the first nine holes, refusing to play a second round because of the pain. She did not play golf again until five days later, June 16. During the first seven holes she noticed some pain in her right side, and this was much more severe when she got a long drive with the wooden clubs. When she drove from the eighth tee she "suffered a terribly sharp pain, as if some one were cutting the right side open with a knife." The eighth and ninth holes were finished, but under great pain. While taking her shower after the game she noticed a swelling in the right side and, because of this and the pain, she sent for her physician. He was unable to attend her at once, and she went to a formal tea, where she "did nothing but try to protect her injured side from the crowd." That evening she attended a dinner party, later driving 25 miles by motor car to her home, where she arrived in partial collapse. The next day she remained in bed under the influence of stimulants and sedatives.

During the five days between the two games of golf the patient suffered chills on two different nights. Once during that week she went swimming and was able to dive three or four times without noticing pain. She entered the hospital, June 18, seven days after her first attack of pain and two days following the second attack, under the diagnosis of strangulated ovarian cyst, or tubal pregnancy. In this connection it should be stated that her menstruation had been regular, occurring every twenty-eight days, of from five to six days' duration, the last two periods having occurred, April 24 and May 25, respectively.

On examination the abdomen was flat, firm, soft and elastic, except for a somewhat indefinite mass or resistant area just above Poupart's ligament on the right side. This area was tender and painful. Vaginally, the uterus lay in retroversion, and was normal in size and freely movable. The left appendage was prolapsed, but on the right side a fixed, tender mass the size of an orange was palpable. The most notable thing about this mass was that it appeared to lie in the anterior pelvis, as if anterior to the round ligament, or, as described in the case record, behind Poupart's ligament.

The patient experienced no chills while under observation; her temperature ranged from 99.5 to 100.2 F., and the leukocyte count was 12,000. After two days' observation, an operation was performed. The skin of the abdominal wall showed no discoloration, but as soon as the subcutaneous fat was reached, an extensive ecchymosis was evident, involving the fat, aponeurosis and right rectus muscle. The structures were not only discolored but also infiltrated and swollen, and between the lower portion of the muscle and its deep fascial sheath lay several ounces of clotted blood. This was removed and revealed the muscle fibers, not divided sharply but as if shredded, and there was some separation of the muscle bundles longitudinally. This area, as it involved the muscle, extended from the symphysis for 10 cm. upward. There was no active bleeding. The ecchymosis involved the peritoneum, which, though markedly discolored, was smooth and shiny on its inner surface, and extended farther into the right round and broad ligaments. This discoloration was apparent throughout the right pelvic wall as far down as the uterosacral ligament, but stopped short of the tube, ovary and uterus by a sharp line of demarcation. The uterus and its appendages were normal.

Since the preparation of this report I have been permitted by Dr. Carl Beck to include one more case:

An Italian woman, obese, about 40 years of age, who had had six children, was suffering from a severe bronchitis. She had coughed hard for several days, when she began to experience pain in the upper right quadrant of the abdomen. Examination showed a hard, tender swelling, the size of a hen's egg. Vomiting, jaundice and constipation were absent. A diagnosis of gallbladder disease was made. An operation revealed that the mass was a hematoma in the sheath of the rectus muscle, just beneath the free edge of the ribs. There was some laceration of muscle fibers but no active bleeding. The peritoneum was not opened.

The obstetric significance of rectus hematoma is interesting. That it occurs rarely is evident, since there are but ten cases in Wohlgemuth's series. At first thought this is surprising, in view of the fact that in pregnancy the recti are more or less under tension and often diastatic. On the other hand, the patients are in the first half of life, before the tissues have become less elastic. The immediate causes, in most cases, are the same as those appearing in the nonpregnant. In Stoeckel's two cases the hemorrhage was occasioned by coughing. One patient was a quartipara in the sixth month of gestation; the other, a sextipara at term, labor not having begun.

Toft's patient, a tertipara, was 30 years old and pregnant six months. She had had bronchitis for several weeks and coughed freely at times. For three weeks there had been pain in the right lower abdomen. This suddenly became severe, and a resistant area developed to the right of the enlarged uterus. The next day there were anemia and signs of ileus. Rupture of the pregnant uterus was feared. At operation a cavity seven inches (213 cm.) long was exposed, filled with blood coagula, in the rectus sheath. The mass had ruptured intraperitoneally, with much free blood in the abdominal cavity. This is the only case reported in which the hematoma had broken through the serous coat.

The patient whose case Sjoblom reported was at the end of her pregnancy, and the accident of rupture was ascribed to no definite cause. In Mace's case the hematoma developed during pregnancy. Vogt's patient was a secundipara, 21 years of age. The hematoma was bilateral, and was discovered after spontaneous labor and ascribed to it. Lichtenstein reported a case in which, after normal labor, the rupture was discovered, correctly diagnosed and treated conservatively. The patient was a primipara, 32 years of age.

Schumann's patient, on the contrary, was a septipara, 44 years of age and obese. Strictly speaking this was not a case of spontaneous development but, because of its interesting diagnostic features, is added to the series. During the last pregnancy she sustained an injury, striking the edge of an open door heavily with the right side of the abdomen. Severe pain and disability followed, but the symptoms disappeared within a few days. Occasional attacks of pain in the right side persisted, and after labor a distinct mass was evident in the right lower quadrant. Within three months ascites developed, with dyspnea and edema of the legs. For the ascites, tapping had been done six times. A large tender mass was palpable in the right iliac fossa, but vaginal examination revealed no deep pelvic abnormalities. A provisional diagnosis was made of some rapidly growing form of generalized malignancy. After the ascitic fluid had been drained from the abdomen, no intraperitoneal disease was found. Within the substance of the rectus muscle lay a huge, old hematoma, after the removal of which the torn end of the deep epigastric artery was found. In this case the injury was due to external violence and occurred during pregnancy, but marked symptoms did not develop until after labor. It is the only case in which ascites occurred.

Andrews' report includes three cases, the second and third of which have been noted.[20] His first case was that of a woman, aged 30, who had been well previously except for acute rheumatism in adolescence. The illness occasioning the report occurred while she was suffering from a severe cough and was propped up in bed. There was sudden pain in the right lower quadrant of the abdomen, which became increasingly severe. The patient was eight months pregnant and noticed no abdominal enlargement disproportionate to the duration of gestation. She was anemic and looked ill. The temperature was 101 F.; the pulse rate, 135, and respirations, from 28 to 36. The cough and dyspnea were severe, and urinalysis showed albumin and casts. A large, tender, dull swelling bulged into the right flank and was palpably separate from the uterine enlargement. A diagnosis was made of hydronephrosis. Thirty hours after admission, premature labor took place. The diagnosis was then changed to inflammatory ovarian cyst, and one week later, when the patient's condition had improved, an operation was undertaken. The tissues beneath the skin were ecchymotic and the swelling was found to be entirely in the abdominal wall, representing old clotted blood, filling a large space behind the rectus and extending up as far as the ribs.

---

[20] Brief abstracts of the twenty-seven cases heretofore described appear in the complete paper as published in the proceedings of the American Gynecological Society, 1925.

Further evidence of the obstetric importance of this condition is seen in the fact that the majority of the patients not pregnant had borne children. Twelve were pregnant or recently delivered, at the time the rupture took place. Of the twenty-nine others, fifteen had had children, the parity of thirteen was not stated, and only one was set down as a nullipara.

SUMMARY

Twenty-nine of the patients were not pregnant, and twelve were pregnant or recently delivered, at the time of the rupture.

Of the twenty-nine who were not pregnant, thirteen were over 50 years of age, seven between 40 and 50, and six under 40. The ages of three were not stated.

Coughing due to bronchitis or influenza was given as the immediate causal factor in eleven cases, ordinary bodily movements in five, and unusual muscular exertion, in the form of hard work, in six. No apparent cause (muscular effort) was seen in three cases, and in two others there was a struggle to keep the balance in falling. Vomiting preceded the rupture in one patient, and in only one was participation in athletic exercise the factor.

Arteriosclerosis was a known condition in one patient, heart disease had been present in two, and hemiplegia had occurred sometime previously in one other.

Obesity was emphasized in nine of the reports, but in nineteen the constitutional build was not stated. One patient was not obese.

Fifteen of the patients had had children, most of them, several. In thirteen reports parity is not mentioned; in one only was the patient described as a nullipara.

One of the outstanding features is that of diagnosis, in most cases the true condition not being recognized prior to operation. In six cases the diagnosis was that of appendicitis; in seven, ovarian cyst with twisted pedicle; in two, appendicitis or ovarian cyst; in two, ovarian tumor, and in two, gallbladder disease. In three cases the preoperative diagnosis was not stated. In one case each the condition was thought to be mesenteric embolism, intraperitoneal disease, intestinal obstruction, abdominal hernia, desmoid tumor and ectopic pregnancy. In only three cases was rectus hematoma diagnosed, and in only two others was it suspected.

The treatment is conservative, if the hematoma is small. If the accumulation of blood is large enough to require evacuation, if it has become infected or if it has ruptured into the peritoneal cavity, operative intervention is indicated.

INTENSITY OF HOOKWORM INFESTATION IN ALABAMA

ITS RELATIONSHIP TO RESIDENCE, OCCUPATION, AGE, SEX AND RACE *

W. G. SMILLIE, M.D.
AND
D. L. AUGUSTINE, Sc.D.
NEW YORK

Hookworm infestation is one of the major public health problems of Alabama. Here the parasite has a wide distribution, for scarcely any county, town or village that has been studied has been found free of infestation. Among children of school age the incidence ranges from less than 5 per cent. in some of the larger towns to 95 per cent. in the heavily infested rural communities.

Formerly, every case of hookworm infestation has been considered hookworm disease, and the public health plan of organization has been to treat every child until he is entirely free from parasites.

Recent studies [1] have shown, however, that the important factor in hookworm disease control is not the incidence but the intensity of infestation from the point of view either of an individual or of a community. The great proportion of persons with hookworm infestation of slight degree suffer no measurable harm, and should be considered not cases of disease but carriers. Practical experience has shown that hookworm carriers should not, in fact, cannot be controlled by treatment, but can best be controlled, and eventually eliminated, by sanitation. Treatment should be used only to reduce the intensity of the infestation in actual cases of hookworm disease to an "economic cure"; i. e., to a carrier state.

This conception requires that a resurvey be made of hookworm infested areas to determine not the incidence, but the intensity, of hookworm infestation, in order that a practicable plan of hookworm control may be formulated which will be effective and economical.

The purpose of the present investigation was the determination of the intensity of hookworm infestation in Alabama. Since Alabama is similar to the whole group of south coastal plain states in climate, economic conditions, geological formation, and type and distribution of population, we hoped that the information obtained and the conclusions drawn might be of general application in these other Southern states.

METHODS OF PROCEDURE

An intensive study was first made of Covington County, in southern Alabama, which is a heavily infested area. The major portion of the work was devoted to the study of children of school age. Such an index would not be satisfactory in the tropics, where adults are more heavily infested than children, but in the southern United States the children of school age represent the most heavily infested age group. A study of the school children, therefore, does not give us a true cross section of the hookworm intensity of the Southern states, but represents a study of the most heavily infested age group.

The Willis salt flotation method was used in determining whether or not a person had hookworms. To

[1] Smillie, W. G., and Augustine, D. L.: The Effect of Varying Intensities of Hookworm Infestation on the Physical Condition of School Children, to be published.

determine the intensity of infestation, ova counts were made by the Stoll procedure on all positive stools. The children were grouped arbitrarily according to the estimated number of hookworms harbored, as follows:

Group 1, negative.
Group 2, very light infestation: from one to twenty-five worms.
Group 3, light infestation: from twenty-six to one hundred worms.
Group 4, moderate infestation: from 101 to 500 worms.
Group 5, heavy infestation: from 501 to 1,000 worms.
Group 6, very heavy infestation: from 1,001 to 3,000 worms.

Only one ova count was made on each child. A second or third ova count would have lowered the probable error of our grouping somewhat, though not to any great extent. In a previous experiment a large number of children were examined twice by the Stoll method, in November and again in February. In only a very few instances was there any variation in the grouping of those children that had received no hookworm treatment between the stool examinations.

The factors considered in relation to intensity of infestation were residence, occupation, age, sex and race.

Following the intensive study of a heavily infested area, a general survey was made of the whole state of Alabama. In this survey another factor was found to be of great importance in relation to intensity of infestation; namely, type of soil. The study of the relation of type of soil to hookworm intensity will be made the subject of a subsequent paper. In the following pages we shall discuss the relationship of each of the factors mentioned above to the degree of hookworm intensity, first in the heavily infested area of Covington County, south Alabama, and then in the state as a whole.

Table 1.—*Intensity of Infestation of 664 Rural and Urban White School Children in Covington County, South Alabama; All Ages (6-16 Years)*

Group	Description	Rural 444 Percentage of Children in Each Group	Urban 220 Percentage of Children in Each Group
1	No hookworms	3.6	55.9
2	Very light infestation, 1-25 hookworms	15.3	15.0
3	Light infestation, 26-100 hookworms	24.5	22.0
4	Moderate infestation, 101-500 hookworms	42.5	5.9
5	Heavy infestation, 501-1,000 hookworms	7.8	1.0
6	Very heavy infestation, 1,001-3,000 hookworms	6.3	0.0

OCCUPATION AND RESIDENCE IN RELATION TO HOOKWORM INTENSITY

The people of Alabama may be divided into two groups: first, those who live in villages and towns; and second, those who live in the rural districts and are engaged in agriculture or allied occupations. The school children have been used as the index of hookworm intensity. We have included in our urban group all school children living in even the small villages (250 or more). The rural children are those who live on scattered farms. It would be more concise to use the terms "farm children" and "village or town children."

The relative intensity of infestation of rural and urban white children in Covington County is shown in Table 1. Chart 1 presents the data of Table 1 in graphic form. The striking difference in the intensity of hookworm infestation of rural and town children in an area favorable to heavy hookworm infestation is clearly shown.

In Table 2 is given the intensity of infestation of negro children of Covington County. There is little difference in the intensity of the negro farm and village groups. In the villages and towns the negroes live in the outskirts and spend much time in the fields. There is much migration between farm and village, so that there is no real distinction between the rural and the urban child.

It will be noted from Table 2 that in Covington County, where there is a high intensity of infestation in white children, only a very small proportion of the negroes are heavily infested. This will be considered under a separate heading.

Table 3 shows that though the intensity of infestation in school children for the state as a whole is much less in Covington County, nevertheless, the relative degree of intensity in farm and village children is the same as in the heavily infested areas. The town children have either a light or no infestation, whereas a large proportion of the country children are infested, many of them having true hookworm disease. Some of the heavily infested town children have moved in from the country within two years. If these heavily infested cases were ruled out, the difference in intensity in rural and urban children would be still more striking.

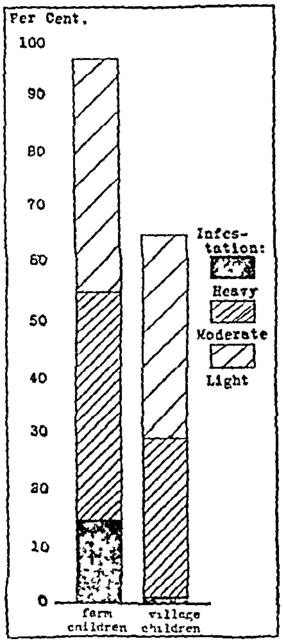

Chart 1.—Higher intensity of hookworm infestation of farm children than of village children of southern Alabama The differentiation in shading is the same in Charts 1, 2, 3 and 5

The towns do not have good sanitation throughout. The center of the villages may have sewerage, but more than one half of the homes have only open-back toilets. Wherever people live in close proximity, however, decency prevents a promiscuous pollution of the soil, as is the universal custom in the country, and thus village children have little opportunity to come in direct contact with infested soil.

Table 2—*Intensity of Hookworm Infestation in Negro Children of Covington County, South Alabama (6-16 Years)*

Group	Description	Rural 117 Percentage of Children in Each Group	Urban 97 Percentage of Children in Each Group
1	No hookworms	39.0	45.2
2	Very light infestation, 1-25 hookworms	30.9	28.3
3	Light infestation, 26-100 hookworms	20.6	18.9
4	Moderate infestation, 101-500 hookworms	8.0	3.2
5	Heavy infestation, 501-1,000 hookworms	0.9	2.0
6	Very heavy infestation, 1,001-3,000 hookworms	0.0	1.0

Though the economic status of the villages is somewhat better than that of the rural districts, it is customary for the children of the rich as well as those of the poor to go barefoot during the summer months, so that the wearing of shoes is not a factor in preventing infestation in the village children.

We may conclude from these tables that village and town children in Alabama have a much lower intensity of infestation than children living on the farms. Even in southern Alabama, where the soil is most favorable to development of hookworm larvae, less than 7 per cent. of the village children have an infestation greater than Group 3. Previous studies[1] have shown that these light infestations produce no measurable harm in growing children and are of little economic importance. But more than 50 per cent. of the rural children in the same area have true hookworm disease. From these tables, therefore, we may draw our first conclusion; namely, in Alabama, hookworm infestation of sufficient intensity to become an economic factor in the lives of the people is limited to persons living in the rural districts on the scattered farms. In general, persons in towns and even in small villages (250 population) do not have true hookworm disease.

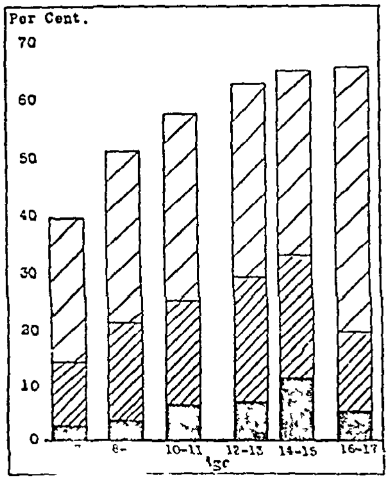

Chart 2.—Relation between age and intensity of hookworm infestation in 1,158 white children in Alabama

AGE IN RELATION TO INTENSITY OF HOOKWORM INFESTATION

The relationship between age and intensity of hookworm infestation is shown in Table 4. This table includes white children only and represents samples taken from all parts of Alabama. Chart 2 represents Table 4 in graphic form

Table 3.—*Difference of Hookworm Intensity in Farm and Village Children in Alabama as a Whole; 1,284 White Children and 555 Negro Children*

		White		Colored	
Group	Description	Rural Per Cent	Urban Per Cent	Rural Per Cent	Urban Per Cent.
1	No hookworms	37.1	63.8	76.1	64.8
2	Very light infestation, 1 25 hookworms	12.6	11.9	13.8	19.1
3	Light infestation, 26 100 hookworms	16.7	17.7	6.1	10.4
4	Moderate infestation, 101 500 hookworms	26.0	5.1	3.0	4.3
5	Heavy infestation, 501 1,000 hookwoms	4.1	1.0	0.3	1.2
6	Very heavy infestation, 1,001-3,000 hookworms	3.3	0.7	0.3	0.0

If we consider incidence of infestation only, Table 4 shows that 38 per cent of the 6 to 7 year old children are infested, and that there is a gradual increase in the percentage of infested children which reaches a maximum in the oldest age group, from 16 to 17 years. If, as formerly, every case of infestation is to be considered hookworm disease, then our most serious condition would be found in the highest age group of the series. But percentage of infestation gives us a false conception of true conditions. When we study the intensity curve and not the incidence curve, we find that only a very small proportion of 6 to 7 year old children have true hookworm disease. The intensity increases gradually year by year, but the maximum is reached not in the 16 to 17 age period but in the 14 to 15 year age period, and there occurs a rapid decline in hookworm intensity in the 16 to 17 age group.

This type of intensity curve in relation to age has the same tendency in all the groups studied. This is shown in Table 5, colored children of Alabama; Table 6, rural white children of Covington County only; Table 7, urban white children of Covington County, and Table 8, negro children of Covington County. Chart 3 is a graphic representation of Table 6 A.

Light infestation	3	12.0	19.6	22.0	38.0	0	0
Very light infestation .	2	8.0	16.3	11.9	23.5	0	0
Negative . . .	1	79.0	55.4	61.0	26.4	100	100

Adult findings are not included in this analysis. We have made a large number of examinations of adults, and with one or two rare exceptions we have found that adults, even in a zone of heavily infested soil, have either no hookworms or at most a very light infestation. The same is true of children under 6 years of age. Light infestation in rural children below school age is common, but heavy infestation in little children is rare.

Table 7.—*Relation Between Age and Intensity of Infestation in 212 Colored Children of Covington County Only, Combined Rural and Urban**

		Age					
		6-7 Years	8-9 Years	10-11 Years	12-13 Years	14-15 Years	16-17 Years
Intensity	Group	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Very heavy infestation.	6	0	0	0	0	0	0
Heavy infestation......	5	0	0	1.8	2.0	6.6	0
Moderate infestation...	4	3.4	10.8	3.7	6.4	10.0	5.5
Light infestation.......	3	7.4	16.2	13.2	30.0	16.6	44.4
Very light infestation..	2	33.4	27.0	32.0	25.5	36.6	22.0
Negative	1	65.6	46.0	49.0	36.2	30.0	27.7

* Because of the small number of cases and the small difference in the intensity in rural and village children, the cases were combined in one group.

Table 8.—*Hookworm Incidence in Relation to Age in Brazil and Southern States of North America**

	Average Number of Hookworms	
	Brazil Worm Counts	Alabama, Whites, Only, Stoll Ova Count Estimation
4- 5 years........	0.5	...
6- 7 years........	14	6.6
8- 9 years........	26	91
10-11 years........	85	138
12-13 years........	169	144
14-15 years........	159	198†
16-17 years........	119	94
18-19 years........	185	24
20-29 years........	165	Very light infection only
30-39 years........	175	Very light infection only
40-49 years........	163	Very light infection only
50-59 years........	64	Very light infection only

* This table illustrates two important facts: 1. Hookworm infestation is slowly acquired and slowly lost. 2. The single factor of wearing shoes may be the determining one in the intensity of hookworm infestation.
† Shoes worn from this time.

The data presented are sufficient to indicate the trend of the age curve of intensity of infestation in Alabama. In Chart 4 we have superimposed the extended intensity curve of Alabama on the intensity curve of the various age groups of Brazil. The Brazilian curve is taken from data presented in Monograph 17 of the Rockefeller Institute for Medical Research.

The two curves correspond closely until the 16-17 age period, when the Alabama curve reaches a maximum followed by a rapid decrease in intensity. The Brazilian curve reaches its maximum at about 24 years, and remains quite constant for a long period. The remarkable universal decrease of hookworm intensity in Alabama children is due to the custom of beginning the constant use of shoes at about 14 years among the whites, a little later among the negroes. No new infestation is acquired, and the old parasites gradually die out in from three to five years. This single factor of wearing shoes is in all probability largely responsible for the absence of heavy infestations in rural adults in Alabama.

These tables substantiate the general law, which was suggested to us by our Brazilian studies;[2] namely, that hookworm infestation is slowly acquired and slowly lost. Heavy hookworm infestation is not acquired in a day or following a single exposure, but is gradually accumulated over a period of years, the old worms slowly dying out and new ones being gradually acquired. As a general rule, a heavily infested case represents long and continuous exposure to infested soil. The tables also show that so simple a factor as wearing shoes, even though they may be rough and coarse, may be the determining factor between severe disease or simple light infestations.

SEX IN RELATION TO INTENSITY OF HOOKWORM INFESTATION

Our studies have shown that there is little or no difference in the intensity of infestation of boys and girls in Alabama. This is to be expected, as the sanitary habits and customs and the mode of life of rural boys and girls are similar up to the age of maturity. Our Brazilian studies showed a corresponding similarity in the intensity of infestation of the two sexes up to adult life. There was a marked difference in intensity of infestation of adults of Brazil, the men having a much heavier infestation than the women. A similar condition was noted by Warren and Carr[3] in Mexico. This difference in intensity between the sexes in adult life does not occur in Alabama because both boys and girls begin to wear shoes at about the same age, and both sexes have a very low intensity in adult life.

From the facts at hand, we may now extend our first conclusion and assert that hookworm disease as an economic burden on the life of the people of Alabama is limited to the rural children of school age.

RACE IN RELATION TO INTENSITY OF HOOKWORM INFESTATION

There is a marked difference in the intensity of hookworm infestation in the white and negro races in Alabama. The Southern states are an ideal place to make such a study, particularly the rural districts of southern Alabama, where conditions are favorable for a high intensity of infestation. Here the two races live side by side on adjoining farms, under very similar economic and sanitary conditions, yet sharply separated by racial distinctions. In Table 9 we have compared the intensity of hookworm infestation of white and negro children in six different areas in Alabama. Chart 5 is a graphic representation of Table 9. Table 10 compares the intensity of infestation of rural white and negro children of a heavily infested area. Here the same difference in the two races is noted.

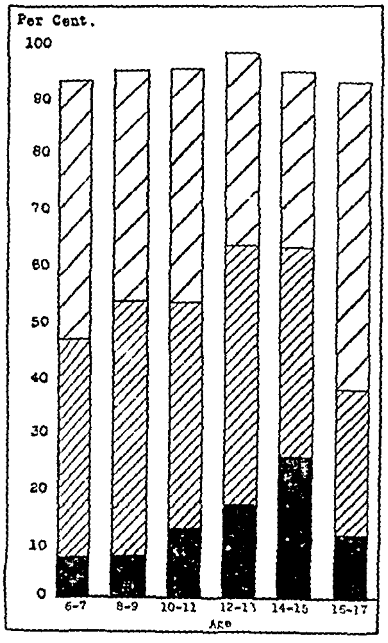

Chart 3.—Relation between age and intensity of infestation in white children in Covington County only; 444 rural children.

---

[2] Smillie, W. G.: Studies of Hookworm Infection in Brazil, Monographs of the Rockefeller Institute, No. 17, 1922.

[3] Personal communication to the authors.

Knowlton,[4] in his hookworm studies at Camp Jackson, S. C., also noted lighter hookworm infestations among the negro than white soldiers from the Carolinas and Florida, using the worm count method. Among sixty-nine white and eighteen colored cases, the average number of worms obtained from the whites was 155.3 and from the colored 38.3, which indicates an infestation about four times greater among the white than among the colored soldiers.

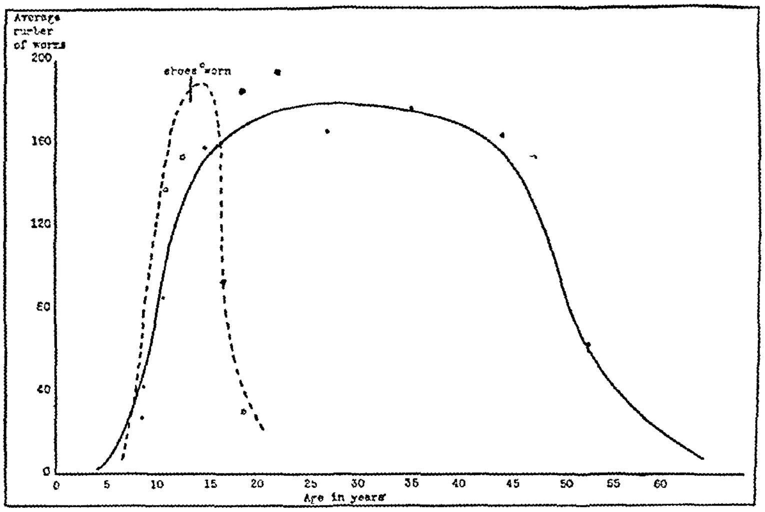

Chart 4—Hookworm incidence in relation to age, comparing Brazil and Southern states of North America. solid line, Brazil, broken line, Southern states

We have no explanation of the fact that negro children have a much lighter infestation than the white children. Our belief is that it is due to a physiologic difference in the two races, namely, the much greater thickness of the epidermis of the negro. Dr. Darling[3] feels that it may be due to slightly different sanitary customs. Dr. Payne[3] believes that it may be due to racial immunity. Rincon,[5] in Colombia, found a higher infestation rate in whites. His results are probably due to better social and economic status and better living condition of the whites in Colombia.

TABLE 9.—*Intensity of Hookworm Infestation in Relation to Race in Six Different Counties in Alabama—Rural Children*

Group	Intensity Group	White, 887 Cases, Percentage of Total Cases	Negroes, 375 Cases, Percentage of Total Cases
1	Negative	37.1	79.5
2	Very light infestation, 1-25 hookworms	12.6	10.1
3	Light infestation, 26-100 hookworms	16.6	6.5
4	Moderate infestation, 101-500 hookworms	25.9	3.5
5	Heavy infestation, 501-1,000 hookworms	4.1	0.2
6	Very heavy infestation, 1,001-3,000 hookworms	3.3	0.2

TABLE 10—*Comparison of Intensity of Hookworm Infestation in the White and Negro Rural School Children of Covington County, Southern Alabama (6-16 Years of Age)*

Group	Description	White, 444 Children, Percentage of Cases	Negroes 117 Children, Percentage of Cases
1	Negative	3.6	39.0
2	Very light infestation, 1-25 hookworms	15.3	30.9
3	Light infestation, 26-100 hookworms	24.5	20.6
4	Moderate infestation, 101-500 hookworms	42.5	8.0
5	Heavy infestation, 501-1,000 hookworms	7.8	0.9
6	Very heavy infestation, 1,001-3,000 hookworms	6.3	0.0

Our results show clearly that when the two races are living under almost identical conditions of sanitation, economic status, occupation, soil, temperature, etc., the whites may have a heavy infestation, whereas the negroes have a very light infestation. In fact, we have found scarcely a case of infestation in a negro in Alabama which was severe enough to produce clinical symptoms. These observations on hookworm infestation in white and negro children have suggested several lines of investigation to us, which are now being pursued.

COMMENT

From the evidence submitted we believe that we are justified in the conclusion that true hookworm disease as a real economic menace to the welfare of the people in Alabama is limited to the rural white children of school age. Hookworm infestation is widely distributed among all age, social, economic and racial groups. The persons with light infestations are not to be ignored, for they are hookworm carriers and are potential sources of danger to the community. They are not cases of hookworm disease, however, and should not be considered as such. If these facts are true for Alabama, they are probably also true for the other coastal plain Southern states having a similar type and distribution of population, and similar climatological and geological conditions.

This conception, if accepted, logically requires that we modify our plan of hookworm control in the Southern United States. Hookworm treatment should not be given indiscriminately to every person who shows a positive stool. It is unjustifiable and unfair to submit such a person to the discomfort of a rigorous hookworm treatment when he is harboring only a small number of hookworms which are doing him no measurable harm. It is poor public health organization to waste time and money on treatment of a community for hookworm infestation when that infestation is causing the community no economic loss.

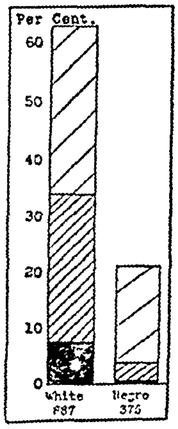

Chart 5 — Intensity of hookworm infestation in relation to color among the rural children in six different counties of Alabama

Hookworm treatment should be employed as a weapon to combat and control true hookworm disease. It should not necessarily be pushed until all persons treated reach the point of microscopic cure. If one standard[6] treatment is given to moderately infested patients and two such treatments to those heavily infested, the group infestation will be reduced to the point of economic cure, in that the intensity of infestation of the treated patients becomes so light that they are carriers and do not have true cases of hookworm disease.

---

[5] Rincon, J. D: Anotacione sobre la anemia tropical en Colombia considerada como problema social y como entided patologica, Estudo de Tesis, Facultad de Medicina Republica de Colombia, 1924

[6] A standard hookworm treatment is considered as a treatment that will remove from 90 to 95 per cent of all hookworms harbored, in a single administration The effective dose of thymol, betanaphthol, oil of chenopodium, carbon tetrachlorid and ascaridol has been determined

Sanitation and education must be the chief modes of control of the carrier. Long experience by many workers has clearly shown that treatment alone is of little avail in the control of incidence of infestation in an area favorable to development of hookworm larvae.

PLAN FOR HOOKWORM CONTROL IN THE SOUTHERN UNITED STATES

The logical plan of public health procedure in hookworm control in the Southern states therefore is to:

1. Control the carrier. Proceed methodically and systematically in the education of the people in regard to the mode of hookworm infestation, and push vigorously the installation of sanitary toilets throughout the rural areas of the Southern states.

2. Limit treatment to actual cases of hookworm disease in rural white school children. This can readily be done by making an ova count estimation of intensity of infestation of rural white school children as a routine part of the regular annual or biannual examination of school children. All persons with light infestations may be advised that they are carriers but do not need treatment. Hookworm treatment need be administered only to those with moderate or heavy infestations. One standard treatment may be administered to children falling in Group 4, two treatments to those heavily infested, Groups 5 and 6.

If such a plan were followed, hookworm disease as a real menace to the people of the Southern states could readily be kept under control by the public health organizations already existing in the various states as a part of the routine procedure in the medical examination and correction of defects of school children.

This method or any other method of treatment will not reduce the incidence of infestation for any considerable period of time. Hookworms will not disappear from the Southern states until the habits and sanitary customs of the rural people are completely changed. Hookworm incidence will diminish slowly year by year as the general principles of sanitation radiate from the towns and villages to the remote rural districts. But only with the improvement of economic conditions in the rural sections of the South, and betterment in educational advantages for the rural children, will it be possible to win complete control over hookworm infestation in the Southern United States.

61 Broadway.

The Surgeon.—There is an unexplainable mental process that precedes what is known as a surgical inspiration, or to use an undergraduate's vulgarism, a surgical "hunch." This means nothing more than that after blindly puzzling and agonizing over a difficult problem in the effort to determine just what course to pursue, there is a sudden and unaccountable clearing of obscurities, and an operator enters upon his task with a conviction of just what he will encounter and just what will happen, as though he were possessed of a sixth sense. I think most surgeons are more or less conscious of this state of mental preparedness for what to others may seem a desperate throw. But there is nothing uncanny about it; it is little more than the subconscious fusion of past experience which concentration brings to bear on a given problem. And as these inspirations in difficult cases are the outgrowth of personal and repeated bedside studies of the patient whose equation also enters into them, he who neglects this portion of his work and merely operates at the behest of another misses much.—Harvey Cushing.

COMPOSITION OF IMPORTED BOTTLED WATERS*

A. E. MIX AND J. W. SALE
WASHINGTON, D. C.

During the fifteen years prior to the beginning of the World War in 1914, the annual receipts of foreign mineral waters amounted to about 3,000,000 gallons, valued at about $1,000,000. There was a marked decrease in receipts during the World War and for several years thereafter, but since 1920 there has been a gradual increase so that at the present time we are receiving about one-fourth the quantity imported prior to the World War. During the twelve months ending in June, 1924, there were imported 753,831 gallons, valued at $281,402.[1] The value of domestic waters sold annually during the last twenty-five years has remained about the same, that is, in the neighborhood of $5,000,000, so that possibly the value of imported waters may in the course of time rise to the former figure of $1,000,000 annually.

In a study of the composition of a large number of mineral waters, it is necessary to classify or group them according to the kind and quantity of dissolved mineral matter contained in them. A number of elaborate and no doubt excellent scientific systems of classification have been devised and are used to a limited extent, but none of them seemed to be suited to our present purpose, which is to classify the mineral waters imported into the United States in a manner which will be readily understood by physicians and others who have not been trained to interpret water analyses expressed in the form of acid and basic ions. It should not be inferred that we do not approve of classification of waters based on acid and basic ions or radicals, but it has been our experience in connection with the enforcement of the Federal Food and Drugs Act that such classifications are not well understood except by chemists. In all of our legal work we have found it necessary to report our analyses in grains per U. S. gallon or grains per U. S. quart of salts, which have been calculated by combining the acid and basic ions according to a definite procedure which will be described later.

In our examination of hundreds of foreign and domestic waters, we have observed that most of them can be placed in one or another of the following five classes, when the analyses are expressed in the form of salts:

Class 1. Dolomitic limestone predominating.
Class 2. Vichy type, sodium bicarbonate predominating.
Class 3. Sodium chlorid predominating.
Class 4. Epsom and Glauber's salts, one or both predominating.
Class 5. Chalybeate or iron type.

The names of these five classes indicate quite clearly the general character of the mineral waters placed in them, but they do not show the approximate quantity of the dissolved mineral matter in a given quantity of the water. Therefore, the five classes described above have been further subdivided into (A) those waters which contain less than 1,000 mg. per liter (or less than 58 grains per U. S. gallon); (B) from 1,000 to 5,000 mg. per liter (or from 58 to 292 grains per U. S. gallon); (C) from 5,000 to 10,000 mg. per liter

---

* From the Water and Beverage Laboratory, Bureau of Chemistry, U. S. Department of Agriculture.

[1] Monthly Summary of Foreign Commerce, Part 1, June, 1924.

(or from 292 to 584 grains per U. S. gallon); (D) from 10,000 to 20,000 mg. per liter (or from 584 to 1,168 grains per U. S. gallon); (E) over 20,000 mg. per liter (or over 1,168 grains per U. S. gallon).

In further explanation of the five classes enumerated above, we might point out that the mineral matter in the waters in Class 1 consists chiefly of limestone (calcium carbonate) or of dolomitic limestone (calcium, magnesium carbonate) held in solution by carbon dioxid, which is usually present in sufficient quantity to prevent precipitation, especially when the bottles are kept closed. Waters of this class are usually rather lightly mineralized and are quite generally employed whenever light, mildly alkaline waters are indicated.

Class 2 comprises the Vichy type of waters, in which bicarbonate of soda is the predominating mineral constituent. They usually contain also a considerable amount of sodium chlorid, together with smaller amounts of a great variety of other salts.

Class 3 consists of waters in which sodium chlorid predominates. Some of the waters in this class, like those in Class 4, are very highly mineralized.

Class 4 comprises those waters in which the dissolved mineral matter consists chiefly of Epsom and Glauber's salts. They are frequently called bitter waters.

Class 5 consists of waters that contain substantial amounts of iron salts. We have included in this class all of those waters which contain 10 mg. or more per liter (or $^{58}/_{100}$ grain or more per U. S. gallon) of iron salts. These waters are termed chalybeate or red waters. The iron is present usually as ferrous bicarbonate and is held in solution by carbon dioxid. When the carbon dioxid escapes, the iron precipitates in the form of ferric oxid. In order to keep bottled waters of this type clear and sparkling it is necessary to bottle them with an abundance of carbon dioxid and to exclude carefully all traces of oxygen.

We have given no consideration to content of radioactivity, for the reason that we have never examined a natural water which contained more than infinitesimal amounts of radium.[2] Also, we have given no consideration to the presence of traces of iodin, bromin, barium and arsenic, which are present in a limited number of the more highly mineralized waters.

The principal acid and basic ions of the mineral waters which are classified in this report have all been combined according to the procedure recommended by the Association of Official Agricultural Chemists,[3] which in part is as follows: Assign sodium, magnesium, calcium and iron in the order given, to the acid ions in the following order: chlorid, sulphate, carbonate and bicarbonate. Therefore, the analyses of these mineral waters are comparable with one another, and subject to classification. These waters have all been analyzed in the Water and Beverage Laboratory of the Bureau of Chemistry, the samples having been collected over a period of years from shipments offered for entry into the United States.

A list of all foreign waters analyzed by the Bureau of Chemistry since the beginning of the enforcement of the federal Food and Drugs Act in 1907, classified in the manner described above, is set forth below.

IMPORTED MINERAL WATERS CLASSIFIED ACCORDING TO CHEMICAL COMPOSITION

Class 1.—*Dolomitic Limestone Type* (predominating constituents being the bicarbonates of calcium and magnesium)

A. Total dissolved mineral matter less than 1,000 mg. per liter (or less than 58 grains per U. S. gallon).

Borgofranco	Ivrea, Italy
Brambacher (Shiller) (also Class 5 A)	Brambach, Germany
Cachat (Evian)	Evian-les-Bains, France
Corallo	Leghorn, Italy
Corticello	Bologna, Italy
Deux Reines	Aix-les-Bains, France
Excelsiorquelle (also Class 5 A)	Bohemia, Czechoslovakia
Fiuggi	Rome, Italy
Graus	Barcelona, Spain
Harzer Königsbrunnen (also Class 5 A)	Goslar, Germany
Harzer Sauerbrun Grauhof (also Class 4 A)	Goslar, Germany
Harzer Victoria	Goslar, Germany
Hirone	Osaka, Japan
La Cotorra	Havana, Cuba
La Francesca	Rionero, Italy
Lourdes	Lourdes, France
Monopole (de la Ville)	———, Belgium
Monticchio Gaudianello	Potenza, Italy
Neudorfer (Duke of Beaufort)	Carlsbad, Czechoslovakia
Nocera Umbra Angelica	Nocera Umbra, Italy
Pejo (also Class 5 A)	Trentino, Italy
Perrier	Vergeze, France
San Miguel, La Salud	Azores, Portugal
Solares (also Class 3 A)	Madrid, Spain
St. Simon (also Class 2 A)	Aix-les-Bains, France
Wernarzer	Brückenau, Germany

B. Total dissolved mineral matter from 1,000 to 5,000 mg. per liter (or from 58 to 292 grains per U. S. gallon).

Ausonia (Bognanco)	Domodossola, Italy
Badoit	St. Galmier (Loire), France
Cambrunnen	Hamburg, Germany
Castellammare di Stabia	Castellammare di Stabia, Italy
Claudia	Rome, Italy
Eptinger	Eptingen, Switzerland
Ferrarelle	Riardo (Caserta), Italy
Flavia	Fiume, Italy
Godesberger (also Class 2 B)	Godesberg, Germany
Hersfelder Lullusbrunnen	Hersfeld, Germany
Hollandia (also Class 3 B)	Haarlem, Netherlands
Italiana (Elena)	Rionero, Italy
L'Insuperabile (Three Star) (also Class 2 B)	Rionero, Italy
Maternidad (also Class 4 B)	Havana, Cuba
Minerva (also Class 3 B)	Naples, Italy
Montecatini Tettucio (also Class 3 B)	Montecatini (Lucca), Italy
Montecatini Torretta (also Class 3 B)	Montecatini (Lucca), Italy
Monticchio (S. Maria de Luco)	Potenza, Italy
Neuselters (also Class 3 B)	Nassau, Germany
Orezza (also Class 5 B)	Corsica, France
Paradiso	Arezzo, Italy
Pliniana	Caserta, Italy
Polenai (also Class 2 B)	Czechoslovakia (formerly Szolyva, Austria-Hungary)
Radeiner Heilquelle (also Class 2 B)	Steiermark, Austria
Roccallaura (also Class 4 B)	Barcelona, Spain
Rudolfsquelle (also Class 5 B)	Czechoslovakia

Salvatore	Caserta, Italy
Salvator	Eperjes, Czechoslovakia
Sangemini	Naples, Italy
San Hilario Sacalm	Gerona, Spain
Santos (also Class 5 B)	Brzvany u Loun, Czechoslovakia
Sodener Warmbrunnen III	Taunus, Germany
Telese	Solopaca, Italy
Traficante	Rionero, Italy
Uliveto	Pisa, Italy
Verniere	Lamalou-les-Bains (Herault), France
Vitolo Salerno	Salerno, Italy
Vittel, Source Grand	Vosges, France
Vittel, Source Hepar	Vosges, France
Vittel, Source Salee	Vosges, France
Weinbrunnen (also Class 5 B)	Langenschwalb, Germany
Wildunger-Königsquelle	Wildungen, Germany
Wildungen-Helenen Quelle (also Class 3 B)	Wildungen, Germany
Wildungen-Georg Victor Quelle	Wildungen, Germany

CLASS 2.—*Vichy Type* (predominating constituents, bicarbonate of sodium with more or less *chlorid of sodium*, etc.)

A. Total dissolved mineral matter less than 1,000 mg. per liter (or less than 58 grains per U. S. gallon).

Borines	Barcelona, Spain
Caxambu (Empreza)	Geraes, Brazil
Neuenahrer Sprudel	Neuenahr, Germany
Plombieres (also Class 4 A)	Plombieres, France
Porla (also Class 5 A)	Laxa, Sweden
Ramlosa	Ramlosa Brunn, Sweden
St. Simon (also Class 1 A)	Aix-les-Bains, France
Teplitz	Bohemia, Czechoslovakia

B. Total dissolved mineral matter from 1,000 to 5,000 mg. per liter (or from 58 to 292 grains per U. S. gallon).

Apollinaris	Neuenahr, Germany
Arienheller	Rheinbrohl, Germany
Bilin	Bilin, Czechoslovakia
Brault	Sail-sous-Couzan (Loire), France
Bullidors Els	Barcelona, Spain
Cabrierora	Orense, Spain
Ems Kranchen	Ems, Germany
Espido (Fuente Nueva de Verin)	Verin, Spain
Fachingen	Nassau, Germany
Fonte Italiana	Rionero, Italy
Franzens (also Classes 4 B and 5 B)	Franzensbad, Czechoslovakia
Glashager	Doberan, Germany
Godesberger (also Class 1 B)	Godesberg, Germany
Imperial Honningen (also Class 3 B)	Coblenz, Germany
Kaiserbrunnen (also Class 3 B)	Offenbach, Germany
Klösterle Sauerbrunn	*Bohemia, Czechoslovakia*
La Bourboule Choussy (also Class 3 B)	Puy-de-Dome, France
La Bourboule Perriere (also Class 3 B)	Puy-de-Dome, France
L'Insuperabile (Three Star) (also Class 1 B)	Rionero, Italy
Mattoni's Gieshubler Sauerbrunnen	Bohemia, Czechoslovakia
Mondariz	Mondariz, Spain
Monteverdi	Siena, Italy
Pedras Salgadas	Rio de Janeiro, Brazil
Polenai (also Class 1 B)	Czechoslovakia (formerly Szolyva, Austria-Hungary)
Radeiner Königsquelle	Steiermark, Austria
Radeiner Heilquelle (also Class 1 B)	Steiermark, Austria
Rhenser (also Classes 3 B and 5 B)	Rhens, Germany
Radiovka	Bohemia, Czechoslovakia
Rocafort	Lerida, Spain
Sabroso	Vidago, Portugal
Saint Mart (also Classes 3 B and 5 B)	Royat, France
Salus Vidago	Vidago, Portugal
Salzbrunnen Oberbrunnen	Silesia, Czechoslovakia
Stahlquelle Franzensbad (also Class 5 B)	Bohemia, Czechoslovakia
Vichy Andreau	Vichy, France
Vichy Catalan	Vichy, France
Vichy Dubois	Vichy, France
Vichy Grande Grille	Vichy, France
Vichy Grande Source	Vichy, France
Vichy Lardy	Vichy, France
Victoria Oberlanstein	Ems, Germany
Vidago	Vidago, Portugal
Vilajuiga	*Gerona, Spain*
Villaza	Orense, Spain

C. Total dissolved mineral matter from 5,000 to 10,000 mg. per liter (or from 292 to 584 grains per U. S. gallon).

Bikszadi	Bikszad, Roumania
Ciappazzi	Messina, Italy
Maria (also Class 5 C)	*Szatmar Nemeti, Roumania*
Margit (also Class 5 C)	Czechoslovakia (formerly Szolyva, Austria-Hungary)
Polenai (also Class 1 B)	Czechoslovakia (formerly Szolyva, Austria-Hungary)

FURUNCLE OF THE NOSE

REPORT OF A CASE RESULTING IN SEPTICEMIA, TREATED SUCCESSFULLY BY INJECTIONS OF MERCUROCHROME *

THOMAS J. HARRIS, M.D.
Professor of Laryngology, New York Post-Graduate Medical School and Hospital
NEW YORK

Dr. Harris P. Mosher's[1] paper of a year ago on unsolved problems in otolaryngology was stimulating in the extreme and contained many valuable observations. Among the unsolved topics which Dr. Mosher did not mention, there is one which, although seemingly inconsequential, is apt to be followed by such serious complications that it deserves to be included among the rest. I refer to furuncle of the nose. The literature on this common infection is surprisingly meager; indeed, I am acquainted with only one paper on the subject, that by Dr. Lee M. Hurd.[2]

During the past winter, we have had under our care a young girl who, as the result of a nasal furuncle, developed general septicemia.

REPORT OF CASE

M., a girl, aged 15, was admitted to the Post-Graduate Hospital, Oct. 15, 1924, for a swelling on the right side of the face which started as a pimple in the nose on that side. This was incised by the physician, who was called in five days previous to admission. Her condition rapidly became worse, the swelling involving the entire side of the face and the upper and lower eyelids. Intense pain accompanied the swelling. On admission, the temperature was 105 F., pulse 130, and respiration, 30. Examination at that time showed an abscess of the lower lid with a normal fundus oculi. Six days later, October 21, a systolic murmur was detected at the apex; a moderate number of râles were heard throughout the chest, and a friction pleuritic rub was heard over the left side of the chest, posteriorly. Based on this, a diagnosis was made by the consulting internist of "pleurisy and of possible beginning pneumonia. Prognosis, not good." Two days later, October 23, a patch was detected in the left lower lobe.

Immediately on admission, the nose and cheek were explored. Through the opening previously made in the right ala, a small amount of pus was evacuated and a gauze drain inserted. At the time of admission, the blood culture was negative and remained so for nine days. October 27, twelve days after admission, a staphylococcemia was demonstrated: red blood corpuscles, 4,100,000; white blood corpuscles, 14,000; differential, 86 per cent. The fundus continued clear with no signs of meningitis and no exophthalmos. The day after admission, the temperature rose to 106, and in the next two weeks was exceedingly high, never falling below 104 the first week and 103 the second week. Abscesses developed below and above the outside of the orbit, requiring incision and drainage. October 17, 800 c.c. of blood from an immunized donor was given. Two days later, 26 c.c. of a 1 per cent. solution of mercurochrome-220 soluble was administered. This was repeated at intervals of two or three days, altogether four times. The temperature slowly fell until December 6, seven weeks after admission, it was 100 by rectum. During this time, the pulse remained steadily high, never falling below 130 and often reaching 150 and 160.

Three weeks after admission, the left ankle began to pain and swell. Cold applications caused the swelling to subside. Following the first administration of the mercurochrome, there was improvement in the general condition with a negative blood examination each time. A second transfusion of 800 c.c. was given eight days after the first. The patient was discharged from the hospital, convalescent, December 9. One month later, she returned, stating that she was still very weak and recently had been having headaches and nausea. Examination with regard to the temperature, blood and nose was negative, but a pronounced anemia was found. The case was not regarded as a surgical one, and the patient was transferred to the medical ward, where a low order of meningitis was suspected. She left the hospital after two weeks, somewhat improved.

COMMENT

This case is instructive on a number of accounts. First, because of the etiology—an innocent appearing pimple in the nose of a healthy young girl following an incision on the third day gave rise to a swelling which extended to the cheek and eye, accompanied by high fever. There were numerous foci of suppuration with staphylococcus infection of the blood, septic pneumonia and endocarditis, with recovery at the end of two months. Except for the fortunate recovery, the history of the case is not unusual although while cases occur undoubtedly with much frequency, accurate reports are lacking in the literature. The match that sets fire to the conflagration sometimes is the opening of the furuncle by a physician, as in this case. At other times no incision has been made, but the patient has picked off the scab with his dirty fingernail and squeezed out the contents of the furuncle. This was the history in a case of cavernous sinus thrombosis which Dr. Herzig[3] reported recently, and also of a similar case reported by Dr. Heller.[4] Dr. Heller also reported a fatal case of cavernous sinus thrombosis following a furuncle of the right ala nasi in which no incision had been made and treatment consisted only of hot applications.

The usual outcome is the fatal one which occurred in the cases of Dr. Heller and Dr. Herzig. The all important question is the reason for this. Incising furuncles or picking them open under septic conditions elsewhere in the body is not wont to be followed by such alarming consequences. While the infection usually is staphylococcic, it is not invariably so. Cases have been reported in which the organism was a streptococcus. There must be some explanation for this introduction into the system of pathogenic bacteria. The blood drainage of the nose in this area is through the facial vein. This connects, by means of the angular vein, with the ophthalmic veins of which there are two, the superior and the inferior. At the inner angle of the orbit, the superior ophthalmic is wont to anastomose with the inferior ophthalmic, and the common trunk passing through the sphenoidal fissure empties into the cavernous sinus. The peculiar feature of these veins, according to Gerrish, is that they have no valves and that under certain conditions the blood may flow from behind forward. Cavernous sinus thrombosis is the most common complication, although meningitis and septicemia also occur. This disease also occurs following carbuncle of the upper lip. We have, then, a sufficient explanation to account for the infection that takes place. Bacteria always are present in the vestibule of the nose and, introduced traumatically or finding their way spontaneously along the hair follicles, enter the blood stream. The retrograde course of the blood stream in veins without valves is sufficient to do the rest.

PROGNOSIS

The course of nasal furunculosis when blood infection has taken place in the past has been almost uniformly fatal. Preventive treatment based on one of the anatomic data just given is important. All interference with a boil inside the nose is to be avoided. The use of a dirty needle followed by squeezing is highly reprehensible. Any measure that has favor for boils elsewhere can be employed here. Phenol (carbolic acid) and a strong solution of an ichthyolate preparation are among those finding especial favor. The procedure of Hurd possesses much merit. He uses warm applications inside and outside the nose followed by incision of the furuncle to a very limited extent and the use of suction. When symptoms of invasion of the blood stream show themselves, the method recommended by Bullack[5] is decidedly appealing. Basing his treatment on the anatomy of the part involved, he advises tying the facial vein at a point from 1½ inches to three-fourths inch below the inner canthus of the eye to prevent cavernous sinus thrombosis. He has employed the method in at least one case with most satisfactory results. The statistics that he has collected of complications following carbuncle of the upper lip are startling, twenty-seven cases with six deaths, three of them due to cavernous sinus thrombosis. He recommends, in advanced cases, ligation also of the superior ophthalmic vein. When thrombosis of the sinus actually has occurred, until recently no successful method for its cure had been devised, although based on the surgical relations Mosher among others has developed one through the orbit where the approach is comparatively easy. The result, however, of Eagleton's work,[6] "twenty-two cases with recovery" after cleaning out the thrombus preceded by ligation of the common carotid, is decidedly encouraging.

My own case, fortunately, was not one of thrombosis. It offered problems, however, almost as difficult of solution. The general septicemia and metastases that followed at one time seemed to render the outcome a hopeless one. In the judgment of all who observed the case, the final recovery was due to the use of mercurochrome-220 soluble, 5 mg. per kilogram of the body weight in a 1 per cent. solution, as recommended by Young,[7] who was the first to employ it. His results in septicemia were so encouraging that the solution has been used by a number of observers for desperate blood conditions, with corresponding good results. In all, four injections were given, none of them followed by any untoward results. In spite of the fact that there are cases on record of acute nephritis following its use, any unqualified statement that the cure was due to the mercurochrome cannot be made because of the fact that the patient had two transfusions. Basing my opinion, however, on the remarkable benefit secured in this single case, I would strongly recommend its use under similar circumstances.

PYOCYANEUS MENINGITIS AFTER LUMBAR PUNCTURE

REPORT OF A CASE WITH APPARENT RECOVERY *

ISIDORE I. LEVY, M.D.
BALTIMORE
AND
ARMAND E. COHEN, M.D.
LOUISVILLE, KY.

Meningitis, apart from the epidemic form, is not infrequently caused by the tubercle bacillus, the pneumococcus and the streptococcus. So far as we were able to ascertain, the case presented here is the first reported case of *Bacillus pyocyaneus* meningitis following lumbar puncture, not preceded by or associated with other pyogenic infection and in which the patient apparently made a complete recovery.

We hope that the presentation of this case may reemphasize the necessity of strict aseptic technic in doing lumbar puncture and outline a method that may prove of value in the treatment of pyocyanic meningitis.

REPORT OF CASE

A. K., a white man, aged 32, entered the Hebrew Hospital of Baltimore, Dec. 15, 1924, complaining of severe frontal and crown headaches.

In 1914, the patient had been treated for pulmonary tuberculosis in a state sanatorium. In 1918, he contracted syphilis and gonorrhea. He complained of girdle pains across the upper abdomen in 1922, and in 1923 he noted weakness and shooting pains in the lower extremities and was unable to walk for six months. At this time, the spinal fluid Wassermann reaction was four plus and globulin one plus, although repeated blood Wassermann tests were negative. Following antisyphilitic treatment, Dec. 5, 1924, a spinal puncture was performed. The cerebrospinal fluid obtained was clear and had a normal cell count, and the Wassermann reaction was negative. The following day, December 6, the patient complained of frontal headaches with pain and stiffness of the neck and back. These symptoms increased in severity, and for several days prior to admission the patient found but little relief even after the administration of morphin.

On admission to the hospital, the patient was fairly well nourished, was conscious, and cried out in pain. There was some slurring of speech and a sluggish response to questions. There was marked rigidity, tenderness and limited motion of the neck. There was photophobia, and the pupils reacted sluggishly to light and in accommodation. There was marked diminution of somatic sensory response. Kernig's sign was positive on both sides; Romberg's sign was negative and the gait was not ataxic. There was fibrosis of the apexes of both lungs and some signs of activity. The pulse was 92; the temperature, 104 F.; the respirations, 24; the systolic blood pressure was 108; diastolic, 52. The urine showed a trace of albumin but no casts. A blood examination revealed: leukocytes, 20,500; polymorphonuclear leukocytes, 80 per cent.; lymphocytes, 14 per cent.; large mononuclears, 6 per cent. The blood culture was negative. The blood Wassermann reaction was: water bath, negative; icebox, four plus. On admission, 30 c.c. of a slightly turbid cerebrospinal fluid was removed under considerable pressure. The cell count was 3,550, and the polymorphonuclear leukocytes, 93 per cent. A gram stain showed gram-negative bacilli. A carbolfuchsin stain was negative for tubercle bacilli. The spinal fluid Wassermann reaction was negative. The globulin reaction by Pandy's method was one plus. A culture of the fluid gave a pure growth of *Bacillus pyocyaneus*. The following day, 25 c.c. of spinal fluid was removed under increased pressure. The spinal cell count was 2,480; polymorphonuclear leukocytes, 92 per cent. A culture taken with sterile technic yielded a pure growth of *Bacillus pyocyaneus*, and the spinal fluid on standing thirty-six hours became a brilliant green. During the first few weeks of the patient's illness, lumbar punctures were done every other day and the spinal canal drained almost completely. As the patient improved, the spinal drainage was done less frequently. Jan. 19, 1925, the first of eight interval doses of intravenous neo-arsphenamin was given. February 14, 10 c.c. of inactivated autogenous blood serum was given intraspinally A similar dose of 14 c.c. was given, March 4, and a third dose of 10 c.c. was given, March 7. Each time an equal amount of spinal fluid was withdrawn.

Spinal Fluid Examinations

Date	Leukocytes	Polymorphynuclears Per Cent.	Mononuclears Per Cent.	Culture
12-15-24	3,500	93	7	B. pyocyaneus
12-17-24	2,480	92	8	B. pyocyaneus
12-19-24	2,750	88	12	B. pyocyaneus
12-21-24	1,450	86	14	B. pyocyaneus
12-23-24	876	78	22	B. pyocyaneus
12-25-24	875	82	18	B. pyocyaneus
12-27-24	140	71	29	B. pyocyaneus
12-29-24	260	60	40	B. pyocyaneus
12-31-24	412	52	48	No growth
1- 2-25	216	44	56	B. pyocyaneus
1- 5-25	100	0	100	No growth
1- 8-25	544	0	100	No growth
1-13-25	74	0	100	No growth
1-15-25	840	0	100	No growth
1-19-25	33	0	100	No growth
1-22-25	48	0	100	No growth
1-26-25	24	0	100	No growth
1-31-25	18	0	100	No growth
2- 7-25	6	0	100	No growth
2-21-25	8	0	100	No growth
2-28-25	12	0	100	No growth
3- 7-25	9	0	100	No growth
3-10-25	56	0	100	No growth
3-24-25	12	0	100	No growth

The early course in the hospital was characterized by hyperexia, leukocytosis, marked loss of weight and headaches relieved temporarily by spinal drainage. The patient remained mentally clear throughout practically the entire course of the disease. March 26, the temperature became normal and remained practically so thereafter. At this time the patient's appetite increased; he gained weight rapidly and complained of no more headaches. The patient was discharged, April 25, apparently cured.

COMMENT

Meningitis caused by *B. pyocyaneus* after lumbar puncture is of extremely rare occurrence. Sonnenschein,[1] in 1923, reported one case of a robust young man who, a few hours after a lumbar puncture which had shown clear fluid, developed symptoms of acute suppurative meningitis, which proved fatal on the eleventh day. The fluid during life and after death showed only *Bacillus pyocyaneus*.

Abadie and LaRoche[2] reported, in 1918, a case of pyocyaneus meningitis in which the disease followed a skull wound. Treatment was by intraspinal injection of the patient's own serum, which apparently cured the young man when the spinal fluid and blood serum contained *Bacillus pyocyaneus*. Three applications of this serum were made, 3 c.c. of the patient's serum being injected at intervals of eighteen and five days.

Chauffard and LaRoche,[3] in 1917, reported a case of tetanus in which intraspinal treatment was given, and the patient developed *B. pyocyaneus* meningitis. The course was relatively benign and cure resulted. There was no pyocyanic septicemia, and the authors considered this case the first of its kind to be reported.

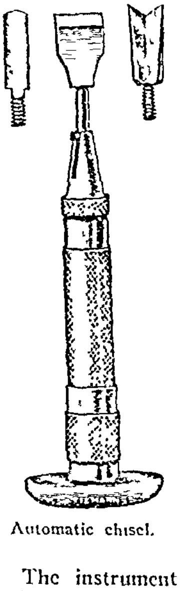
We are not unmindful of the fact that *B. pyocyaneus* is a less virulent organism than others in the pyogenic group, and the favorable outcome of our case may be due in a large measure to the lesser virulence of this infective agent. In this case, the excessive headaches were relieved by the spinal drainage, and we think that this procedure, together with the intraspinal injection of inactivated autogenous blood serum, had a favorable influence on the course of the disease.

Clinical Notes, Suggestions and New Instruments

AN AUTOMATIC CHISEL

David R. Telson, M D , Brooklyn

The chisels shown in the accompanying illustration are constructed on the principles of the steel worker's automatic punch and the dentist's mallet. When pressure is brought to bear on the handle of the instrument, it can be depressed for a short distance, compressing the spring on the inside of the handle. On further pressure the spring is tripped and a short, sharp blow is delivered at the chisel point.



Automatic chisel.

I believe this instrument has particular value in chiseling at the bottom of wounds in which the surgeon desires to keep his examining finger in contact with the chisel head, and finds it awkward to have his assistant use the mallet, yet finds on using the ordinary chisel that it is apt to slip, as it is difficult to gage the exact force that is used when merely pushing the ordinary chisel by hand The instrument can be placed at the site, and merely continued pressure causes it to cut its way through the thickness of the bone. The right angle chisel head is useful in raising bone chips from the lamina of the vertebra in the Hibbs spine fusion. I believe the blow delivered by the spring is much softer and less shock producing than the one that is produced by the mallet, and, therefore, the instrument lessens the objection that is made to the use of the Hibbs spine fusion in Pott's disease by causing less trauma of the diseased area.

The instrument is boilable. However, a drop of sterile olive oil may need to be applied to the inside of the mechanism after several boilings. The force of the blow is regulated by screwing down or releasing the head of the instrument.

GOITER PROPHYLAXIS

Less than a decade has passed since systematic measures for the prevention of simple goiter have been instituted on a large scale in this country in regions where the incidence of such thyroid enlargement directs attention to the local possibilities of "disease due to iodin starvation." Iodin preparations of one sort or another have been employed either unwittingly or in a desultory way in the relief of goiter for many years; but it remained for the investigations of Marine and Kimball, beginning about 1917, to furnish a firm foundation for the current prophylactic practices. Thyroid disease is a many headed monster that has often been attacked in the past as if it were a uniform single entity to be overcome. At no time has the importance of accurate differential diagnosis been more urgent than in these days, when not only medical but also lay publications resound the importance of goiter prophylaxis and present volumes of testimony as to the beneficent effectiveness of the attempts already undertaken in this field. As an illustration of the direction followed by the current enthusiasm, the recently advocated conclusions of Hathaway[1] may be cited. He insists that a program that would control the goiter situation should include detailed surveys of all localities where the disorder is suspected; this is the basis for all successful methods of goiter prevention. He recommends the institution of treatment with sodium iodid of the water supplies of all cities and towns that prove to be goitrous; and he adds that small villages not having a common water supply and rural communities must have the iodin supplied by the use of iodized table salt or by iodin tablets of some kind.

There is admittedly much warrant for such recommendations, which have in fact already been put into operation in certain communities under the sanction of competent professional advisers. Medication for the masses and therapy on a wholesome basis—even uniformity of health-promoting recommendations—call for careful consideration. Exercise that is in general admittedly wholesome is by no means always advisable for every member of the family. Cold air is no longer looked on as a universal panacea, even in pneumonia. "One man's meat is another man's poison" is an old saying with modern implications; to this the varied manifestations of allergy bear witness. May it not be well, therefore, for the medical profession to proceed with due caution in the commendable program of goiter prevention, particularly in view of the fact that its advice is likely to be followed with undue enthusiasm by lay followers who are not accustomed to pay attention to exceptions from a wholesale rule? They often forget the importance of adopting recommendations "with a grain of salt"; all too often they pursue the policy which assumes that if a little is good, more ought to be better.

Experienced students of the goiter problem are issuing corrective warnings, but their concern should not be interpreted as dampening the ardor for the possibilities of preventive measures at this time. A highly important movement for health promotion must not be menaced by possible harm from overenthusiasm. Thus Jackson,[2] who writes from Wisconsin with the conviction of an observer within the "goiter belt," asserts, contrary to reports from other sources, that the number of cases of hyperthyroidism has greatly increased as a result of the popular demand for iodin in the treatment of goiter. Consequently, he advises that the element should not be distributed promiscuously either in water or in salt, but should be administered in exact amounts and under a physician's orders. Jackson insists that even minute amounts of iodin are sufficient to initiate symptoms of hyperthyroidism in certain persons with adenomatous goiters. Iodin should be administered, he adds, with particular care to children with adenomatous goiters; it should never be given to adults with this condition.

Likewise Kimball,[3] recognizing that "there is no consistent pathology of goiter," has expressed the message of caution to the readers of THE JOURNAL. His own studies show that toxic goiters may result from the use of iodized salt in cases of adenomas of long standing; he adds, however, that these cases may be entirely coincidental, and that too much emphasis should not be placed on this point. Instead of advocating promiscuous wholesale administration, Kimball urges that in all cases of iodin treatment the dosage should be considered in terms of milligrams. The maximum dosage for an adult, provided there are no contraindications, is 10 mg. daily for not longer than one month, during which time the patients should be under very close observation. Kimball believes that there is no danger in the routine prophylaxis of goiter as it is carried out through the schools; namely, the administration of 10 mg. of iodin weekly.

[3] Kimball, O. P.: Induced Hyperthyroidism, J. A. M. A. **85**: 1709 (Nov. 28) 1925.

The evaluation of the use of iodin in hyperthyroidism belongs in a separate category, as was recently pointed out in The Journal.[4] Within the last two years the use of iodin in the treatment of exophthalmic goiter has attained a new vogue.[5] This is, of course, a procedure quite different from the now familiar prophylactic use of iodin in relation to adolescent goiter. The claims for its application in exophthalmic goiter are that the drug will produce abrupt remission in most cases. The remission is often as rapid and as extensive as that following subtotal thyroidectomy. However, iodin alone as now used has not been shown to be sufficient to suppress the disease permanently. After a patient with exophthalmic goiter has been taking the drug, a rapid rise of metabolic rate and increase of toxic symptoms may occur within one or two weeks if the iodin is stopped. Furthermore, in some cases of exophthalmic goiter, iodin has no observable effect. According to Rienhoff,[6] the artificial remission of the condition, as it is produced by iodin, is associated with a change of the thyroid from a hyperplastic to a colloid state. Obvious variations may occur through a very wide range of coincident clinical and structural possibilities. Such studies greatly enhance the opportunity to approach the problem of choice of therapy with greater intelligence.

MUSCULAR EXERCISE AT HIGH ALTITUDES

This is not the first time that radical revision of the older conceptions of the energetics of muscular contraction—in other words, of the nature of muscular work—has been referred to in The Journal.[7] One of the early steps was the abandonment of the idea that proteins or other nitrogenous compounds supply the energy for muscular performance; for there is no increment of nitrogenous waste such as might be expected from a breakdown of proteins. For a long time the transformation of energy in muscular work was assumed to be due to the oxidation of carbohydrate, presumably glucose, in the muscle. Perhaps the most radical change of opinion regarding the process has been the abandonment of the theory that this organ is a combustion engine, and the acceptance of the view that it is a chemical machine in which the energy of motion is derived directly from chemical energy.

There was a time when the oxidative metabolism was conceived to be somewhat dependent on the oxygen supply, in the same sense that combustion is accelerated by fanning the flame. It has become a dictum of the science of nutrition, however, that "the absorption of oxygen does not cause metabolism, but rather the amount of the metabolism determines the amount of oxygen to be absorbed."[8] In this connection we have heard of late of the possibility of the body's incurring an oxygen deficit under severe exertion. According to the investigations of Hill and Meyerhof, in particular, the process in muscular contraction is anaerobic; that is, it does not primarily involve oxidation. As a recent writer[9] has described the process, the muscle accumulates its energy in a form known as a lactic acid precursor, glycogen, which is easily and quickly made available at the instant of contraction. The energy becomes available by the transformation of glycogen into lactic acid, and this process is immediately followed by a contraction. Afterward, the lactic acid remains to be reconverted into glycogen or oxidized. In the reconversion process approximately one molecule of lactic acid is oxidized to every five reconverted. If, after contraction, enough oxygen is not available for reconverting the acid into the precursor, then the acid remains, so to speak, as a security for future oxidation. In other words, the amount of lactic acid is a measure of the oxygen debt. This point of view makes it easier to understand how it is possible for a man to take an amount of muscular exercise that requires far more oxygen than can be supplied during the exercise. The oxygen is not used in the process of muscular contraction but afterward during the process of recovery. The muscle is capable of going into debt for oxygen. Thus, Henderson and Haggard[10] have recently shown that an oarsman may exert a power which exceeds by 30 to 60 per cent. that afforded by the oxygen simultaneously absorbed; he thus draws heavily on his credit, and incurs oxygen deficits of from 4 to 8 liters or more; these deficits are repaid by the high rate of oxygen absorption for a time after the work is ended.

It might be expected that a deficiency in the available supply of oxygen would cause the oxygen debt, after a selected load of work, to be larger than when the supply is abundant. The oxygen debt, as ordinarily defined, is determined by measuring the total oxygen used in the selected period of recovery and by subtracting from this the amount of oxygen that the body would have used in the same time during rest. Schneider and Clarke, at the School of Aviation

[10] Henderson, Yandell; and Haggard, H. W.: The Maximum of Human Power and Its Fuel, Am. J. Physiol. **72**: 264 (April) 1925.

Medicine, Mitchel Field, Long Island, have observed that the oxidative processes of the body are retarded at barometric pressures less than 410 mm. The interference of a low barometric pressure with the oxidative processes of the body is accentuated during physical work. The aviation authorities assert that, despite the markedly decreased consumption of oxygen during work at a low barometric pressure corresponding to a very high altitude, it is not shown that the oxygen debt of the body is increased by work at the low pressure. Theoretically, they state, the oxygen debt should be as much larger when work is done under a low pressure as the oxygen consumption at that pressure is less than when the same load is carried at the normal barometric pressure. Such is not the case. In the period of recovery after exercise, the consumption of oxygen is approximately equal after equal loads of work at normal and low barometric pressures. Evidently the body protects itself against an oxygen deficit in the early stages of existence at lowered barometric pressures until various familiar protective devices come into play. The disturbances in the biochemical condition of the body are slowly compensated for, if sufficient time is spent under the new condition to permit the system to reestablish an equilibrium.

SUNSHINE AND HEALTH

There is something appealing in the doctrine of the healthfulness of fresh air and sunshine. It almost seems as though they represent instinctive preferences on the part of mankind so far as modes of living are concerned. These atmospheric factors play a large part in the propaganda of medical climatology, yet it has not been easy to define their potencies in terms of concrete benefits or to describe their functions in the language of scientific endeavor. The demonstration that the sun's rays may destroy certain micro-organisms was welcomed, for it gave the semblance of tangible advantage to sunlight. The antirachitic effects of exposure to sunlight discovered during the last few years indicate the therapeutic and prophylactic efficacy of sunlit air. Hope has been awakened of further advantages to be learned, and warnings have even been issued against the possible harmfulness of overexposure to such types of radiation in the belief that it may be healthful, curative or even injurious, depending on the "dosage."

Among the slowly growing accumulation of measurable facts are data on the interrelation of rickets and rachitic predisposition to climatic factors. This has been stressed before in The Journal.[1] It is not easy to evaluate correctly the relative importance of diet and environment in this connection, especially since the food intake is likely to alter with the seasons and geographic locations, so that what is ascribed to sunshine may in fact be associated with better nutrition depending on dietary changes. Among the recent statistics relating to the composition of the blood—a good index of rachitic tendencies—the data of Riesenfeld, Handelman and Rose[2] are significant. More than a thousand determinations of inorganic phosphorus were made on the blood of mothers and their new-born infants. The investigation extended over a period of fourteen consecutive months, and the data obtained were correlated with the factors causative of rickets. No significant difference was found between the average inorganic phosphorus of the white and negro mothers or of their infants. The inorganic phosphorus of the blood of the new-born infant was not affected by the previous habitat of the mother (that is, tropics or temperate zone). The time the mother spent outdoors during gestation showed no influence on the inorganic phosphorus of the infant's blood. The diet of the mother was one of the controlling factors of the inorganic phosphorus content of the blood of the new-born infants. However, a definite seasonal variation of inorganic phosphorus was noted, which is in harmony with the recognized seasonal incidence of rickets. The curves of available sunlight hours and inorganic phosphorus of the new-born infant are parallel in the latter half of the year, the points of resemblance in the sunlight curve preceding that of the inorganic phosphorus curve by one month.

According to these observers, individual sunlight exposure and the available sunlight in the community were not found to be such obvious causative factors in the inorganic phosphorus of the infant as we are led to expect from the current literature on rickets. On the other hand, these experimenters believe that the relative humidity is strikingly associated with the rise and fall of the average inorganic phosphorus of the infant's blood. In the past, this relation between the humidity and blood phosphorus concentration has not been emphasized. It is suggested that moisture and precipitation may intensify the effect of the ultraviolet rays by increasing their concentration.

In further emphasis of the interrelation of climate and bone development, Moore and Dennis[3] of Portland, Ore., have observed that craniotabes is more prevalent in the Pacific Northwest than in sections of the country having more sunshine. It occurs most frequently during the months of March and April, also being most severe in the spring months. Thus the seasonal incidence of craniotabes in such regions is the same as that of undisputed signs of rickets.

Current Comment

THE BEHAVIOR OF SULPHATES IN THE BODY

The urine contains sulphates in variable amounts ranging, as a rule, from 1 to 2 gm. of sulphur daily. Except under special circumstances these do not arise from preformed sulphates introduced into the organism but are products of its oxidative metabolism. Sulphur is ingested chiefly in the form of protein; the quantities consumed in other compounds are small at most. Between the moment of intake and that of its output this element therefore undergoes, somewhere in the body, chemical reactions resulting in the production of sulphate ions. What happens to them prior to their elimination has been largely a matter of conjecture. With respect to the physiologic migrations of chlorids and phosphates, a considerable mass of information is available; not so in the case of sulphates. A few years ago, Denis [1] of the Tulane University School of Medicine at New Orleans ascertained that sulphates circulate in normal human blood to the extent of from 1 to 0.5 mg. of sulphur per hundred cubic centimeters of blood. She also observed that in nephritic patients there may be a manifold retention of sulphates in the blood. According to Denis and Hobson [2] the sulphate ion occupies a position somewhat similar to that of uric acid as regards ease of excretion by the kidney, whereas the chlorin ion may be compared in this respect to the creatinin fraction; in other words, the sulphate ion appears to be excreted with greater difficulty than does any other inorganic radical ordinarily present in normal blood and, therefore, is retained more frequently and in greater amount than any other inorganic component. The reverse may be said to be true of the chlorin ion, which, on account of its apparent ease of excretion, is seldom retained except in certain cases in which marked impairment of kidney function takes place, whereas the retention of inorganic phosphate may amount to 400 per cent. and of sulphate to as much as 3,000 per cent. of the average normal value. When chlorids are injected into the blood stream, they disappear from it with great rapidity; sulphates, on the other hand, tend to be retained for some time.[3] It is well known that ingested sulphates do not readily penetrate the alimentary barrier; hence they are only slowly absorbed and by their accumulation in the bowel tend to promote laxation. Denis and Leche [4] have now added another chapter to the story of sulphate behavior in the body by the demonstration that the sulphate ions are not readily absorbed by the tissues, even when the blood abounds in them. From this it appears that it is the kidneys alone that exert any noteworthy selective retention of sulphates.

THE PARATHYROIDS AND IODIN

The identification of the parathyroid glands has a sufficiently recent history to excuse some of the confusion that still is current with regard to them. A discriminating anatomic description of these structures was not published until Sandström's work in 1880; thereupon, several years intervened until it was discovered that the parathyroids have a special physiologic significance that is not to be confused with the function of the thyroids. It is not strange, therefore, that when attention was focused on the presence of iodin in the latter glands after the epoch-making research of Baumann in 1895, the parathyroids should have been subjected anew to consideration from the standpoint of this chemical element. Not a little confusion was early occasioned by the fact that iodin was actually reported to be a component of the parathyroids. Presently, conflicting reports appeared. It is quite conceivable that, unless the dissections are carefully carried out, fragments of adherent thyroidal tissue may be included in parathyroid preparations; it is possible, likewise, that iodin may actually be distributed more widely in the body than was at first supposed. The latest evidence secured by Hjort, Gruhzit and Flieger [1] seem to afford an explanation. Histologic examinations have convinced them that there need be no contamination of parathyroid preparations with thyroid tissue at the time of collection from the animal. This is certainly true if the preparations are made from the external bovine glands. Careful chemical analysis on histologically controlled materials has disclosed that the iodin content of the parathyroids is of no greater magnitude than that of the ovaries, pituitary and thymus. The results, indicating from 0.003 to 0.006 per cent. of iodin in the desiccated tissues, were so nearly alike as to warrant the conclusion that only a slight trace of iodin is contained in the glands examined and that the iodin is quite uniformly distributed throughout the animal glandular system, the thyroid excepted. These findings are essentially a corroboration of the majority of past observations; and they suggest that the iodin found in these glands probably represents the normal distribution of that substance throughout the body tissues. Consequently, claims regarding the presence of iodin in commercial parathyroid products should not be allowed to produce any unwarranted implications with respect to therapeutic potencies or properties.

Essentials for Medical Licensure.—It appears to me that it *is essential for the good of the community that all individuals* licensed to treat the sick members of the community should have received the same basal education, and should have passed through practical courses qualifying them to obtain diplomas or degrees. At the present time the minimum curriculum in this country is a five years' course of study after having passed a preliminary examination in general knowledge, and a preregistration examination in elementary chemistry and elementary physics.—Waring, H. J.: Osteopathy, Chiropractic and Medicine, *Brit. M. J.* **2**:682 (Oct. 17) 1925.

Association News

GRANTS FOR RESEARCH

Committee Requests Information Concerning Needs

The Committee on Scientific Research of the American Medical Association announces that applications for grants should be mailed to this committee as soon as possible. Recommendations will be made, Jan. 30, 1926. Applications giving full details may be forwarded to the chairman of the Committee on Scientific Research, American Medical Association, 535 North Dearborn Street, Chicago.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Society News.—Dr. Willard J. Stone, Pasadena, addressed the San Diego County Medical Society, December 8, on "Certain Aspects of Heart Disease," and Dr. James W. Sherrill, San Diego, on "The Parathyroids."——Dr. James F. Percy, Los Angeles, recently addressed the Tulare County Medical Society on "The Modern Treatment of Cancer."——Dr. Steele F. Stewart addressed the Los Angeles Medical Association, Los Angeles, December 3, on "Convalescent Care of Infantile Paralysis."

Personal.—Dr. Aleck P. Harrison has been appointed health officer of Santa Barbara County, to succeed Dr. George S. Loveren.——Dr. Matthew F. Desmond has been appointed health officer of Burlingame.——Dr. Jessie B. Farrior has been appointed resident physician at St. Anthony's Hospital, Oakland.——Dr. Buchanan Caldwell, Biggs, has been appointed health officer of Butte County to succeed the late Dr. Lewis Q. Thompson.——Dr. Philip B. Fry, Benicia, has been appointed health officer of Benicia.

Reinstatement Denied.—At the regular meeting of the California State Board of Medical Examiners, October 20, Sacramento, the petition of Dr. Earl Harlan, Colusa, for the restitution of his license, which was revoked, July 7, was denied. Dr. Harlan was accused of irregularities in regard to narcotics. Dr. Toshio Ichioka, Los Angeles, who was found guilty of illegal advertising, was given three years probation in which to practice on condition that he make his advertising conform to standards of the board.

Prizes for Medical Essays.—The council of the California Medical Association, at a meeting at Long Beach, November 8, resolved to establish two prizes of $150 to be competed for at the 1926 annual convention, one for a paper on original research, the other on a clinical subject, the scope of the material to be determined by the committee. Any member of the state association is eligible to compete, and papers must be submitted before March 19, 1926. Inquiries as to the contest should be addressed to the chairman of the committee, Dr. Walter C. Alvarez, 177 Post Street, San Francisco; other members of the committee are Dr. Dudley Fulton, Los Angeles, and Fred Fairchild, Woodland.

CONNECTICUT

Laymen Health Officers Appointed.—Carolyn Hanchett has been appointed health officer of Canaan, replacing Isaac P. Hornbeck.——Mr. Charles B. Eastman has been appointed health officer of Woodbury, replacing Mr. Charles H. Capewell.——Mr. Marshall E. Case has been appointed health officer of Barkhamsted, replacing Mr. Herbert Case, resigned.

Health Officers Appointed.—Dr. Samuel Bartholomew has been appointed health officer of Goshen, to succeed the late Dr. Caroline North Stevens.——Dr. Lester F. Turney has been appointed health officer of Windsor, to succeed the late Dr. Howard F. King.——Dr. Voyle A. Paul is now acting health officer of Stamford until an appointee is named to succeed Dr. Raymond D. Fear.

Yale to Revise Educational Methods.—The faculty of Yale University School of Medicine, New Haven, is considering the abolition of the year system of study and the division of the student body into classes. Dean Winternitz announced, December 16, that plans are being made to revise thoroughly the educational methods with a view to placing less emphasis on routine class work and more on independent thought and research. The program will involve abolishing the system of examinations at the end of courses. The student will select the sequence of his studies in the first two years of the curriculum, and after qualifying for clinical subjects will again be allowed the liberty of choice. The completion of these studies and their arrangement will be largely a matter of his choice and ability, and his admission to courses will depend on his fitness as determined by the instructor in charge. As a check on the accomplishment of students, there will be group examinations and a graduating thesis, and within reasonable limits the student will determine when he will present himself for such a test.

DISTRICT OF COLUMBIA

Adcox Pleads Guilty in Washington.—Dr. Robert Adcox and Sam Kaplan, St. Louis, pleaded guilty, December 7, in Washington, it is reported, to an indictment charging them with conspiracy to use the mails to defraud; Dr. Ralph A. Voigt, Kansas City, Mo., and "Bishop" Helmuth P. Holler, dean of Oriental University, were indicted with this pair in March, 1924. The government charged, it is said, that they represented Oriental University as a bona fide institution and issued medical diplomas. The catalogue of this school is said to show that about 700 various degrees were issued. "Bishop" Holler's former secretary testified that the "faculty" met once a month to sign diplomas, and that each member received 25 cents per signature. A medical degree is said to have cost $100, and could be obtained in six and sometimes in three months; a degree in dental surgery cost $75 and doctor of divinity, $55. Some of these diplomas exhibited at the trial had government seals, said to have been obtained from certificates issued by the Attorney General's office which indicated that certain persons were notary publics. An alumni association and endowment fund had been started with President Obregon of Mexico heading the endowment fund committee, other members being in Brazil, Japan, Switzerland and other places.

FLORIDA

Increase in Death Rate.—The Department of Commerce announces that the 1924 death rate for Florida was 1,484 per 100,000 population as compared with 1,349 in 1923. The increase is largely accounted for by increases in the death rates from heart disease, pneumonia, automobile accidents and cancer.

The Florida Migration.—About 700 physicians took the June and October examinations to obtain licenses to practice medicine in Florida, according to a statement in the New York *Times*, credited to the Florida state health officer. While the number of physicians is considered sufficient (there were 1,452, Jan. 1, 1925) to protect the public health, the number of tourists living in camps, estimated by the state health officer at 125,000 and by others at as much as 600,000, demands careful consideration. There are 178 certified tourists' camps and an unknown number of small camps. The inspection of these camps is in the hands of a field staff of seven, the legislature having failed to provide funds for more inspectors. There are physicians as full time health officers at Miami, Jacksonville, Tampa, Coral Gables, Lakeland, Fort Pierce, and Hollywood, while West Palm Beach has a layman as health officer, and St. Petersburg and Fort Lauderdale have health officers who are veterinarians. The city of Miami, the most congested place in the state, has twenty-six sanitary inspectors. The general problem of sanitation was taken up December 10-11, at a two-day conference of the League of Florida Municipalities at Orlando, attended by representatives or the mayors of all cities in the state. Local physicians in places having no full-time health officers are devoting part time to municipal health problems. The state health officer, Dr. Burdett L. Arms, stated that every step to guard against epidemics is being taken.

ILLINOIS

Medical Board Objects to Free Immunization.—The medical board of St. Anthony's Hospital, Rock Island, has passed a resolution, according to the Rock Island *Times*, opposing the administration of toxin-antitoxin free of charge to school children under the direction of school physicians; as a result, it is said, the plans of the school superintendent to have pupils immunized against diphtheria have been changed, and family physicians will do the work when requested by parents. The toxin-antitoxin which had been ordered from the state health department will be turned over for this purpose without charge.

Chicago

Society News.—There was a joint meeting of the Chicago Medical Society and the Chicago Roentgen Society, December 16, at which Dr. James H. Hutton exhibited a case of hemochromatosis in a woman, and Dr. Mary E. Hanks read a paper on "Roentgen Ray as a Remedy in Fibroid and Other Benign Gynecologic Diseases."——At the tenth annual meeting of the board of governors of the Institute of Medicine of Chicago, December 9, Dr. Anton J. Carlson, professor and chairman of the department of physiology, University of Chicago, was elected president of the Institute for 1926; Dr. Robert B. Preble, vice president; Dr. George H. Coleman, secretary; Dr. John Favill, treasurer, and Dr. Ludvig Hektoen, chairman of the board.——Dr. William E. Gallie, Toronto, will address the Orthopedic Club, December 22, at the University Club on "Transplantation of Fibrous Tissue in Repair of Anatomic Defects." Dr. Joseph C. Bloodgood, Baltimore, will address the club, January 8, on "A Brief Review of the Salient Points in the Diagnosis and Treatment of Benign and Malignant Lesions of Bone from an Industrial Standpoint."——There was a dinner at the Hamilton Club, December 16, in honor of Dr. Amedee Granger, New Orleans, and Dr. Russell L. Hayden, Kansas City, Mo., who addressed the Chicago Medical Society that evening on "Radiographic Examination of the Mastoids" and "The Value of the Dental Radiograph in Determining Periapical Infection," respectively.

MAINE

Society News.—Dr. John L. Morse, Boston, held a clinic recently before the semiannual meeting of the Aroostook County Medical Society at Fort Fairfield, and in the afternoon addressed the society on "Physical Examination of Children."——Dr. Foster S. Kellogg, Boston, recently addressed the Androscoggin County Medical Society, Lewiston, on "Obstetrics."——Dr. Alfred Mitchell, Jr., Portland, recently addressed the Kennebec County Medical Society, Waterville, on "A Review of Urology."

MARYLAND

Society Election.—Dr. George L. Streeter, chief of the department of embryology of the Carnegie Institute, Washington, D. C., gave an illustrated lecture before the Baltimore City Medical Society, December 4, on "The Miller Specimen, the Youngest Known Human Embryo." Dr. Dean Lewis, Johns Hopkins University Medical School, gave an illustrated lecture on "Surgical Diseases of the Large Bowel"; Dr. Isador C. Rubin, New York, spoke on "Diagnostic and Therapeutic Application of Peruterine Insufflation in Cases of Sterility." At this meeting Dr. William T. Watson was elected president of the society; Dr. E. H. Robertson, vice president; Dr. Edward P. Smith, secretary, and Dr. Charles E. Brack, treasurer.

Infant Mortality Declines; Birth Rate Rises.—A report by Dr. James H. Mason Knox, Jr., chief of the Bureau of Child Hygiene, state department of health, shows a steady decline in infant mortality in Maryland and an increase in the birth rate. Of every five babies born in 1910, one died before reaching 1 year of age, while last year the ratio was one death to every twelve births. Deaths of children under 1 year of age have decreased about 25 per cent. last year as compared with 1910. For the same years, the increase in births is about 60 per cent. In 1910, the first year for which figures were kept by the state deparement of health, 2,169 infant deaths were recorded; last year the total was 1,509. Births in 1910 numbered 10,710, as compared with 17,248 last year.

MASSACHUSETTS

Fellowship in Medicine.—The will of M. Douglas Flattery, Boston, who died November 25, provides for a bequest of $25,000 to Harvard University, which will be held in trust for the M. Douglas Flattery Fellowship and a research fellowship in medicine.

Society News.—Dr. Raphael Isaacs, Huntington, addressed the North Shore Medical Fraternity, November 3, on "Diseases of the Blood and Blood-Making Organs," illustrated with lantern slides.——Dr. Albert Warren Stearns, Boston, psychiatrist to Charlestown State Prison, addressed the Worcester District Medical Society, November 11, on "Conduct Disorders as a Public Health Problem."

Personal.—Dr. Abraham Myerson, professor of neurology and neuropathology, Tufts Medical School, Boston, addressed a meeting at the Chamber of Commerce, November 18, held under the auspices of various industrial societies, on "The Practical Psychology of Business," and Dr. Charles Macfie Campbell, director of the Boston Psychopathic Hospital on "The Mental Health of the Individual Worker."

MICHIGAN

Dr. Darling Honored.—Dr. Cyrenus G. Darling, Ann Arbor, was the guest of honor at a dinner at St. Joseph's Mercy Hospital, tendered by the hospital and staff, on the occasion of his forty-fourth year in the practice of medicine; among the speakers were Harley A. Haynes, director of the University Hospital; Walter H. Sawyer, regent of the University, and Rev. Michael P. Bourke, Detroit. Dr. Darling was presented with forty-four American Beauty roses.

"Minimum Program" for County Societies.—The *Journal of the Michigan State Medical Society* for December publishes the "Minimum Program for County Societies," which the council recently approved and which many county societies have adopted (The Journal, October 17, p. 1230; November 14, p. 1565). The program calls for ten meetings a year, at three of which local speakers will appear with definite planned discussions; each society shall have a "scientific team" of two or three members who will prepare and give a program on request before at least three other societies. The society shall institute a program of physical examinations in which all members shall agree to have a complete physical examination themselves and to secure at least five patients who will be examined. Each society shall have at least one public health lecture group which will give at least five lectures in communities outside their resident communities; each society will assist other organizations so that public lectures may be held one in each high school, one for each parent teacher association, one for each luncheon club, one for each woman's club and one for each association of commerce. There will be at least three dinner meetings at which the speakers will not be medical men, and at least one picnic and one social evening in cooperation with members of closely related organizations. Each meeting of the society shall be reported to the local newspapers in such form that at least one point of value is clear to the reader, and the secretary will report monthly complete records of activities to the state medical society.

MINNESOTA

Personal.—Dr. Audley V. Fankboner, Motley, has accepted the position of superintendent of the Lenont Aurora Hospital, Aurora.——Dr. Alexander J. McRae, Duluth, has resigned as superintendent of St. Luke's Hospital, which position he held for twenty-five years.

Award to Dr. Rosenow.—The Ohio State Dental Society, at the sixtieth annual convention, Columbus, December 2, awarded the Callahan gold medal for 1925 to Dr. Edward C. Rosenow, Mayo Clinic, Rochester, for "outstanding contributions to medical, bacteriologic and dental education."

Society News.—The Hennepin County Medical Society and the Ramsey County Society held a joint meeting, December 7, at the Town and Country Club, Minneapolis, and were addressed by Dr. Arnold Schwyzer on "Surgical Experiences in the Pharyngolaryngeal Area," and by Dr. Frederick H. K. Schaaf on "The Present Status of Stimulation (So-Called Foreign Protein) Therapy." Dr. Orianna McDaniel gave "A Brief Review of Poliomyelitis in Minnesota" before the society, December 9.

MISSOURI

Memorial to Dr. Hypes.—The building committee of the St. Louis Medical Society received a check, November 12, for $7,500 for a memorial for the late Dr. Benjamin M. Hypes, an ex-president, which will be applied as requested, to the "President's Room" in the library.

Society News.—Dr. Frank J. Hall addressed the Jasper County Medical Society, Joplin, November 17, on "Relation of Tissue Diagnosis to Hospital Service," and Dr. Ralph E. Duncan, on "Relation of Laboratory Medicine to General Medicine."——Dr. John L. Yates, Milwaukee, addressed the St. Louis Medical Society, November 24, on "The Biology and Treatment of Cancer."——Dr. Amand N. Ravold was recently elected president of the St. Louis Medical Society; Drs. Charles A. Vosburgh and Floyd Stewart, vice presidents, and Dr. Edwin C. Funsch, secretary.——The Jackson County Medical Society will conduct a symposium, December 15, on "Obstruction of Urinary Bladder Neck" and a symposium, December 22, on "Pernicious Anemia." Prof. Carl F. Nelson, University of Kansas School of Medicine, addressed the society, December 8, on "Cancer—Its Biochemistry."——Dr. Austin B. Jones, Kansas City, addressed the Clay County Medical Society, Excelsior Springs, recently, on "Treatment of Lobar Pneumonia."

The Adcox Confession (Continued).—Branch agencies of the diploma mill having been organized in several cities, Adcox did not have to travel from coast to coast any longer. He had time to develop a new field. He had known for a long time, he says in the St. Louis *Star,* that "big money" could be made in obtaining licenses for "dumb-bells" to practice medicine. Now, after a "thorough investigation," he sent for the "young chap" who offered $1,000 for a license to practice in a Southern state. The offer was repeated and Adcox was assured that the applicant had brains enough to keep out of trouble. Agreeing to take the examination for him, Adcox mailed an application to the board, using the name and address of his client. When the notice to appear was received, he left for the "scene of the big adventure," wondering whether his first attempt in the license market would fail. He finished the "really difficult examination" in two days, and in about a week the "young chap" came to his house with the license and within another week he had rented an office and begun to practice. Adcox says that in a few days he received a dozen requests for licenses. He conferred with Ralph A. Voigt and others, and "one of the men" in his organization promptly "opened up Arkansas." Scores of men ignorant of medicine for the most part—at times enough to warrant the railway to use a special car—made the trip to Little Rock. The names of those who were licensed, he says, can be found in the records. Florida was next to be "opened up." Any one who had a bogus diploma and $500 could get a license there. The examination questions, it is said, were always the same. They were about like these: 1. Are you a doctor? 2. Got a diploma? 3. Do you want to practice medicine in Florida? 4. Can you keep your mouth shut? 5. Did you bring your $500?

When Adcox was taking an examination in the name of another man, a member of the board of examiners tapped him on the shoulder and said, "Come to my office when you finish." The examiner advised Adcox that the next time he came he bring his young men with him and drop into his office the day before the examination. He was told there would be an envelop on the mantel piece in which "you might leave a little something in return for what you find." This meant that Adcox need not handle his applicants one at a time any longer, but that he could bring several, or enough to require a special car. Returning to St. Louis, he looked over the list of men seeking assistance and selected five of the "brightest"; he employed a young doctor who could answer almost any question to help in case of need, and the seven left for the city in the South. Adcox called on the friendly examiner and found a large envelop on the mantel in which was a list of the questions. He took the questions, placed a number of twenty dollar bills in the envelop, and put it back on the mantel. He and the "bright young doctor" then prepared answers to the questions and gave the five applicants each a "pony," which could be concealed in the palm. All five passed and were licensed; some remained in this Southern state to practice, and others after a time went elsewhere with licenses obtained by reciprocity. This board met four times a year; Adcox could not hope, therefore, to obtain enough licenses from this source for all who applied to him, so he took examinations in other states in the names of men of about his age, while Ralph A. Voigt took care of the young fellows in Kansas City. They had on their list several "bright young doctors" who for $500 and expenses would go to any state to take an examination under the name of one of their "clients." Voigt was kept busy taking examinations in Iowa, Illinois, Kansas, Texas, Tennessee, Missouri and other states; he, Adcox says, has taken as many as five prospects into an examination and supplied all of them with answers; when a board required applicants to file their photographs, Voigt would attach a trick photograph of himself to an application which was made out in the name of his client. The photograph would fade in six weeks, leaving a piece of blank paper. Adcox's graft in the Southern state had lasted about a year when his friend on the board of examiners died. Looking about for a new field, he learned that Connecticut had "been opened up."

NEBRASKA

Personal.—Dr. Ethel M. Laybourne has been elected superintendent of the Bryan Memorial Hospital, Lincoln; Dr. Laybourne has been a missionary in India for nine years.

Society News.—Dr. Palmer Findley, Omaha, formerly president of the state medical association, gave a lantern slide lecture on "Puerperal Infection" before the annual meeting of the Eighth Councilor District and Holt County medical societies, O'Neill, October 22. The present officers of the society, Dr. Charles H. Root, Bassett, and Dr. Frederic L. Wilson, Stuart, were unanimously reelected president and secretary-treasurer, respectively.——Dr. James V. Beghtol, Hastings, has been elected president of the Republican Valley and Tenth Council or District medical societies, to succeed Dr. Ralph D. Green, Beaver City.——Dr. Harry Gideon Wells, professor of pathology, University of Chicago, addressed the Lancaster County Medical Society, Lincoln, November 21, on "Heredity in the Relation of Cancer to the Human Species."——Dr. Adolph Sachs was elected president of the Omaha Douglas County Medical Society at the annual meeting, December 8; Dr. Frank M. Conlin, vice president, and Dr. Earl C. Sage, secretary-treasurer.

NEW YORK

Osler Club at Saranac Lake.—The Osler Club, formed at Saranac Lake, held its inaugural meeting, December 9. The purposes of the club include the fostering of good fellowship, stimulation of the study of medical history and the growth of medical libraries; an artistic souvenir program was embellished with selections from the works of Osler.

Veteran Physicians Honored.—The Suffolk County Medical Society, Riverhead, gave a banquet, December 11, in honor of Dr. Clarence C. Miles of Greenport and Dr. Edwin H. Moore of Bay Shore, each of whom has completed a half century in the practice of medicine. The honored guests are still active; Dr. Miles has been recently elected president of the Southold Savings Bank, and Dr. Moore has for many years been coroner of the county.

Society News.—Dr. James S. Ames, Babylon, was elected president of the Suffolk County Medical Society at the October meeting, Riverhead, and Dr. Edwin P. Kolb, Holtsville, secretary. Dr. William St. Lawrence, New York, addressed the society on the use of toxin antitoxin. Dr. Joseph S. Lawrence, executive officer of the state medical society, gave an address. The lectures on psychiatry, approved by the society at the annual meeting, October 29, began December 3 and will continue on Thursdays for nine weeks.——Dr. Smith E. Jelliffe, New York, addressed the annual joint meeting of the Newburgh and Poughkeepsie medical societies at Newburgh, November 17, on "Psychanalysis and Organic Disease."——The New York Society of Orthodontists met at the Vanderbilt Hotel, New York, December 9; the afternoon was devoted to photography, which was discussed, among others, by L. A. Jones, head of the physics department, research laboratory, Eastman Kodak Company, Rochester; the evening session was addressed by Thaddeus P. Hyatt on "Prophylactic Odontotomy as Related to Orthodontia." The next meeting will be in March, 1926, when various committees of the First International Orthodontic Congress will give reports. Charles A. Spahn, D.D.S., 121 East Sixtieth Street, New York, is secretary.

New York City

Personal.—Dr. Hideyo Noguchi received the degree of Doctor, Honoris Causa, November 28, at the Sorbonne, Paris. ——Dr. Charles F. Nichols has been commissioned a major in the U. S. Army Reserve to command the sanitary detachment of the One Hundred and Sixth Infantry.——Dr. Oliver R. Avison, who has been on active duty in Seoul, Korea, since 1893, and is president of the Severence Union Medical College, is at present in New York. Dr. Avison, according to the *New York Medical Week,* spent years in organizing a medical language in Korean and has translated Gray's Anatomy into that language.

Hospital News.—A group of physicians has purchased a site on the west side of East End Avenue between Eighty-Seventh and Eighty-Eighth streets, on which they will build a fifteen-story hospital-hotel.——The board of directors of the New York Post-Graduate Medical School and Hospital held a reception, November 24, to mark the formal opening of the new library.——Sir William Arbuthnot Lane, London, attended the breaking of ground for the clinics building at the new Columbia-Presbyterian Medical Center, November 25. ——The Knickerbocker Hospital has been permitted to mortgage its property for $50,000, which is to be applied on the construction of the new hospital at One Hundred and Thirtieth Street and Convent Avenue.

Proposed Merger of Hospitals.—The New York Academy of Medicine is sponsoring a proposed law to consolidate under one department the control and management of the public hospitals of the city exclusive of those which care for contagious and infectious disease. The bill would place under the hospital advisory board, which is composed of physicians, the scientific management of these hospitals, and would place the business administration, as well as the determination of which patients are able to pay for their care, in the hands of a layman. The purpose of the bill is to relieve physicians of work with which they are not familiar and to give these hospitals the best medical management. The plan has been approved by the mayor and was taken up before the board of estimate branch of the assembly, December 11.

NORTH CAROLINA

Personal.—Dr. William T. Shaver, Badin, has been appointed company surgeon for the Southern Railway, to succeed the late Dr. Jasper N. Anderson, and Dr. George D. Vick, Selma, has been appointed assistant surgeon.

Increase in Death Rate.—The Department of Commerce announces that the 1924 death rate for North Carolina was 1,221 per hundred thousand of population, as compared with 1,197 in 1923. The increase is largely accounted for by increases in the death rates of diseases of the heart (from 112 to 127), pneumonia and nephritis.

OHIO

Gynecologist Appointed.—The board of trustees of the University of Cincinnati, December 1, appointed Dr. Charles L. Bonifield as director of the gynecologic service in the medical school, to succeed the late Dr. Sigmar Stark, and Dr. Henry L. Woodward, acting director of the obstetric service; these were the only new appointments among the directors of services in the medical school; Dr. Carl Koch was appointed an assistant in pediatrics, and Dr. Henry Gruener assistant clinician in otolaryngology, outpatient dispensary. The Mendenhall Scholarship in Obstetrics for 1925-1926 was awarded to Dr. Robert L. Crudgington, resident in the obstetric service at the General Hospital.

Licenses Revoked or Suspended.—The Ohio State Medical Board has taken the action indicated in the cases of the following physicians during 1925:

Charles S. Emery, license revoked, April 6, 1925; reason, conviction of a felony, criminal abortion.

Cassius Minser, license revoked, July 14, 1925; reason, conviction of a felony, criminal abortion.

Addison D. Hobart, license revoked, July 14, 1925; reason, violation of the Food and Drugs Act.

Samuel S. Tomlinson, license revoked, Oct. 6, 1925; reason, conviction of a felony, criminal abortion.

Lloyd E. Overhulse, certificate suspended, April 7, 1925, for sixty days; reason, lending one's name to an illegal practitioner.

Orlo L. Mapes, certificate suspended, Oct. 6, 1925, for sixty days; reason, extravagantly worded advertising.

Charles A. Duff, certificate suspended, Oct. 6, 1925, for sixty days; reason, extravagantly worded advertising, and association with an unlicensed practitioner.

Milk Council Organized.—Dr. John E. Monger, director, state health department, has been appointed chairman of the Ohio Better Milk Council, on whose board of directors are representatives of the state medical association, Ohio Hospital Association, State Association of Graduate Nurses, Ohio Farm Bureau Federation, Ohio State Grange, Ohio Federation of Women's Clubs, Ohio Milk Distributors Association, the College of Agriculture of Ohio State University, the state department of agriculture, and the state department of public instruction. Among the objects of the council are to legally define pasteurization and to punish those who do not comply with the standard established; to determine the conditions surrounding the production and distribution of milk and to have adopted in places where not already adopted the regulations recommended by the state department of health concerning milk, and to recommend that special care be taken in the sterilization of all milk utensils by live steam.

Society News.—Drs. Hugh Cabot, Ann Arbor, Mich., Thomas McCrae, Philadelphia, Charles A. Elliot, Chicago, John F. Barnhill, Indianapolis, Abraham Zingher, New York, and Albert G. Mitchell and Martin H. Fischer, Cincinnati, addressed the Second Councilor District Society at the recent five-day session at Dayton. There was an average daily attendance of nearly 300 physicians from the district; Dr. William B. Quinn, Springfield, was elected president of the society, to succeed Dr. William H. Finley, Xenia; Dr. Arthur O. Peters, Dayton, was reelected secretary, and Dr. Herbert C. Haning, Dayton, reelected treasurer.——Dr. Roy G. Hoskins, professor and head of the department of physiology, Ohio State University College of Medicine, Columbus, addressed the Four-County Medical Society (Fulton, Williams, Defiance and Henry counties) at Wauseon on "Endocrinology and the Physician."——Dr. John M. Ingersoll, Cleveland, addressed the two hundred and third session of the Union Medical Association of the Sixth Councilor District at the College of Worcester, November 10, on "Infections in Nose, Throat and Ear, with a Few Practical Suggestions."

PENNSYLVANIA

Personal.—Dr. John D. Matz, Allentown, was elected president of the Alumni of the Medico-Chirurgical College, at the annual banquet in Philadelphia, November 19.——Dr. John M. Bertolet, Reading, having reached the retiring age, has resigned as a member of the general staff of the Reading Hospital.

Society News.—The fifth annual conference and exposition of hospital supplies and equipment will be held at the Hotel Schenley, Pittsburgh, April 13-15.——Dr. Arthur J. Davidson, associate professor of orthopedic surgery, Jefferson Medical College, addressed the December meeting of the Berks County Medical Society on "The Practical Consideration of the Diagnosis and Management of Joint Tuberculosis."——Dr. Charles H. Miner, state health commissioner, addressed the Lancaster County Health Association, December 16, at Lancaster, on "The Relation of the State Department of Health to the Local Boards of Health."——Dr. Richard J. Behan, Pittsburgh, addressed the Buffalo Academy of Medicine, November 25, on "Correlation of Experimental Research with Treatment in Cancer."

Philadelphia

Society News.—Among others, Dr. Myer Solis-Cohen addressed the Philadelphia Pediatric Society, December 8, on "Removing Bacterial Sites of Infection in the Treatment and Prevention of Endocarditis."

Medical Missionary Society.—The Pennsylvania Medical Missionary Society met, December 2, at the home of Mrs. Charles E. Pugh; about 150 members and guests of the society were present. Dr. Wilfred T. Grenfell gave an address on medical missionary work in Labrador.

Gifts of Hospital Beds.—George W. Nevil has given $5,000 to the National Stomach Hospital, Philadelphia, to endow a free bed in memory of the family of Joseph and Amelia Nevil. Our correspondent writes that Mr. Nevil has given fifteen other similar gifts creating free beds in other hospitals in Philadelphia.

First Pyorrhea Clinic.—With donations from several Philadelphians, a clinic has been established at 2009 Pine Street for the treatment of pyorrhea. It is said to be the first of its kind in this country and will be open to the public from 2 to 5 on Monday and Thursday. A nominal fee will be charged those able to pay.

TENNESSEE

Society News.—Dr. M. B. Hendrix, Memphis, was elected president of the Frisco Railroad Medical Association at a recent meeting in St. Louis.——The Memphis and Shelby County Medical Society voted recently to take no action on the offer of the American Birth Control League to send a lecturer to discuss contraception.

VIRGINIA

Personal.—Dr. Robert P. Cooke has been appointed county health officer of Accomack County. Dr. Richard R. Nevitte, Temperanceville, was elected president of the Accomack County Medical Society at the recent annual meeting.

Chiropractor Sentenced.—Rena M. King, a chiropractor of Richmond, was sentenced, November 21, to sixty days in jail by Justice Ingram on a charge of practicing without a license. On a previous occasion, Justice Ingram fined the defendant $50 and required a peace bond of $1,000 for twelve months. The case was appealed.

Funds for New Medical School.—President Alderman of the University of Virginia announced, December 9, that the General Education Board had appropriated $700,000 to the university for the erection of buildings and equipment for medical science and for properly relating the medical science to the hospital and clinical work already established. The gift is said to be without any further restrictions.

WEST VIRGINIA

Community Cooperation.—The twenty-four bed tuberculosis sanatorium, Eastmont, in Monongalia County, is nearing completion under the auspices of the County Tuberculosis Association. A site having been chosen on the Cheat River road, 3 miles east of Morgantown, the association held conferences with various organizations to obtain their cooperation, and when plans were complete, members of social and civic clubs cleared several acres of grounds; the bricklayers donated their services to lay the foundation; lumber and electrical companies donated materials; the lathers and the plasterers donated their services and some materials; the traction company extended their line to the sanatorium; organizations and individuals contributed several thousand dollars, and the Monongalia County Court appropriated $7,000 for maintenance. The sanatorium, now almost completed, has actually been erected by the community.

CANADA

Personal.—Dr. Alfred Desloges, formerly intern at the Hotel Dieu Hospital, Montreal, has been appointed a fellow in ophthalmology at the Mayo Clinic, Rochester, Minn.——Dr. Reginald S. Henderson of the Tranquille Sanitarium, Vancouver, who has been appointed medical officer for the Engineer Gold Mine, left, November 15, to take up his new duties.——Dr. William Egbert, Calgary, was sworn in as lieutenant-governor of Alberta, October 29, to succeed Dr. Robert G. Brett. Dr. Egbert formerly was president of the Provincial Medical Association and of the Calgary Medical Association.

Dissolution of Canadian Branches.—The council of the British Medical Association has given notice to all concerned of the following resolution passed by the council, October 21. The Canadian branches referred to will be deemed by the council to be dissolved as from June 1, 1926:

> That, following on the adoption by the annual representative meeting, 1925, and extraordinary general meetings of the association, of articles of association as regards affiliation, and the terms of the affiliation of the Canadian Medical Association with the British Medical Association, the council, in pursuance of the power conferred on it by Article 15, do forthwith give notice to dissolve the following branches of the British Medical Association in Canada: Halifax, Nova Scotia; Montreal; St. John, New Brunswick; Saskatchewan; Toronto.

GENERAL

Society News.—Dr. Weston D. Bayley, Philadelphia, was elected president of the American Stomatological Association at the meeting in New York, November 16; Dr. George R. Satterlee, New York, president-elect; Drs. Joseph C. Bloodgood, Baltimore, and Oliver T. Osborne, New Haven, Conn., vice presidents; Dr. Robert H. Rose, New York, treasurer, and Alfred J. Asgis, D.D.S., New York, secretary.——The next annual meeting of the American Gynecological Society will be at Stockbridge, Mass., May 20-22, 1926.

Fellowships for Women.—The American Association of University Women announces fellowships which are open to American women, among which are the Sarah Berliner Research and Lecture Fellowship for women holding the degree of Ph.D., or D.Sc. The value of the fellowship is from $1,000 to $1,200, available for research in biology, chemistry or physics. The association also announces that the Alpha Xi Delta fraternity offers a fellowship of $1,000 for graduate work in the field of medicine or mental science available for the year 1926-1927; it will be awarded by the committee on fellowships of the American Association of University Women. The association offers a $1,200 fellowship to carry on research in some country other than the fellow's own during the academic year 1926-1927. The stipend will be paid half-yearly in advance, and the work can be done in any important university or institution. Applications should be made to the chairman on fellowships, Prof. Agnes L. Rogers, Bryn Mawr College, Bryn Mawr, Pa.

New County Society Presidents.—The following have recently been elected president of the county medical society indicated: Dr. Nelson M. Rhodes, Champaign County Medical Society, Urbana, Ohio; Dr. Lee E. Shafer, Scott County Medical Society, Davenport, Iowa; Dr. Reuben A. Moffett, Knox County Medical Society, Knoxville, Ill.; Dr. Clarence A. Good, Buchanan County Medical Society, St. Joseph, Mo.; Dr. John F. Dunn, Arlington, Ky., Carlisle County Medical Society; Dr. James A. Elliott, Battle Creek, Mich., Calhoun County Medical Society; Dr. Harry A. Neiswander, Pandora, Ohio, of the Putnam County Medical Society, and Dr. Willet W. Binion, Benevolence, Ga., of the Randolph County Medical Society; Dr. Frank A. Fuller, Jacksonville, Texas, the Cherokee County Medical Society; Dr. Francis M. Hartsook, the Vermilion County Medical Society, Danville, Ill.; Dr. Melville F. Boulden, the Clinton County Medical Society, Frankfort, Ind.; Dr. Herman C. Grim, Trumbauersville, Bucks County Medical Society, Pennsylvania; Dr. David Ward Scanlan, Atlantic City, N. J., Atlantic County Medical Society (reelected).

News of Epidemics.—The epidemic of measles in Yonkers, N. Y., December 1, had amounted to 800 cases with five deaths in children under 3 years of age; there were 300 cases in the city on that date.——The health officer of Norristown, Pa., reported a measles epidemic in November of forty-nine cases.——The city health department of Dallas, Texas, reported the closing of the kindergarten in the Fannin school, November 28, on account of an outbreak of scarlet fever.——The Seventh Ward school of Breensburg, Pa., was recently closed on account of an outbreak of scarlet fever and will not reopen until after the holidays.——The city health officer at Oshkosh has excluded from attending high school about twenty male students, on account of an outbreak of scabies; about the same number of girl students was excluded for the same reason.——The health commissioner of Baltimore announced, November 28, that 160 new cases of measles had been reported during the previous week, with two deaths.——Hardin County, Ohio, has had an outbreak of thirty cases of scarlet fever, mostly in Ada, Alger and McGuffey; eighteen cases were still under quarantine, December 1.

Bequests and Donations.—The following bequests and donations have been announced recently:

The Broad Street, Mount Sinai, Mount Lebanon, Presbyterian and St. Vincent's hospitals, all of New York, each $30,000, by the will of the late Mrs. Mathilde G. Sterne, payable after the death of a daughter.

The Southside Hospital, Bayshore, $10,000, and on the death of a daughter a similar amount to St. Vincent's Hospital, the Home for Incurables, Roosevelt Hospital and New York Dispensary, all of New York, by the will of the late William H. Wickham.

The three hospitals for crippled children in Minneapolis and St. Paul, $30,000, by the will of a crippled newsboy, who died in November.

The College of Physicians, Philadelphia, $10,000, by the will of the late Dr. Richard H. Harte, who specified in his will that the income from half of the amount to be used to purchase books and journals for the library, the collection acquired to be known as the Richard H. Harte Book Fund, and that the remainder be set aside to defray the expense of dinners to guests at various meetings.

The Brooklyn Home for the Blind, Port Jefferson, L. I., $1,500, by the will of the late James Burns.

The Hebrew Orphan Asylum, Montefiore Hospital for Chronic Diseases, Mount Sinai Hospital, New York, each $2,000, by the will of the late Solomon Libman.

Mount Sinai Hospital, New York, $1,000, by the will of the late Ida Held.

The New York Hospital, Hospital for Ruptured and Crippled, and New York Skin and Cancer Hospital, each $25,000; the New York Dispensary and St. John's Guild, each $15,000, by the will of Charles H. Rhinelander, who died in 1916, and whose residuary estate was recently accounted in court.

The New York Skin and Cancer Hospital, $1,500, by the will of the late Edward F. Gordon.

The Nursing Sisters of the Sick Poor, New York, $100, by the will of the late Anna A. Boyle.

St. Luke's Hospital, New York, $5,000; St. Mary's Free Hospital for Children; the Knickerbocker Hospital; the Harlem Eye and Ear Hospital, and the Home for Incurables, New York, each $3,000; the Misericordia Hospital and the Society for Relief of the Destitute Blind, each $1,000, by the will of the late Mary C. Van Cott.

The Jewish Hospital, Philadelphia, $5,000 by the will of the late Charles Alexander, to endow a bed to be known as the Charles and Fanny S. Alexander bed.

Kensington Hospital for Women, Philadelphia, $1,000 by the will of Mr. Ellis, who died at Orlando, Fla., last April.

The Newark Memorial Hospital, Newark, N. J., $5,000, by the will of the late Eliza L. Koegel.

Endowments and the Community Trust.—A group of physicians issued a statement, December 10, urging that endowments for medical research or the treatment of the sick or for medical education be kept free from narrow limitations and rigid conditions. It was said that the changing status of medical education and the advance in medical science makes "frozen endowments" of particular concern to the medical profession. In thirteen years, institutional orphanages have increased in the United States at the rate of one about every fifteen days, while the supply of orphans to fill them has shown signs of diminishing. Without deprecating the excellent work of many "asylums," the statement adds, it appears that changes in the problem of caring for dependent children has tended to lessen the need for new orphanages as compared with other social needs. Once endowments take rigid form for some specific purpose, it becomes exceedingly difficult to recast them. To meet the problem arising from "frozen endowments," there has been instituted the plan of the Community Trust, which provides a method of bringing together funds of any size, gives them permanent administration and preserves them from becoming "frozen." Each fund, large or small, constitutes an independent memorial and is placed for investment with any one of various national banks or trust companies, and the expenditures or income from each is supervised by a central distribution committee. While the statement outlines the object of the Community Trust to physicians, a more detailed description can be obtained from Dr. Walter B. James, 7 East Seventieth Street, New York, a member of the distribution committee. The statement is signed by Drs. George Emerson Brewer, Samuel A. Brown, George W. Crile, Charles L. Dana, D. Bryson Delavan, Arthur B. Duel, Emanuel Libman, Charles H. Mayo, William J. Mayo, James A. Miller, Bernard Sachs, Bentley Squier, George D. Stewart, William G. Thompson, Linsly R. Williams and Walter B. James.

FOREIGN

Medical Students in Germany.—The *Münchener medizinische Wochenschrift* states that the total number of male medical students in German universities has declined from 15,500 in 1913 to 7,196 in 1925, while the number of women studying medicine has increased from 868 in 1913 to 1,321 in 1925.

Fourth Autumn Dinner.—About 300 members and guests of the British Medical Association assembled in the Great Hall of the association's new home, October 21, for the fourth autumn dinner, which was in the nature of a house warming. The chairman of the council, Dr. Robert A. Bolam, occupied the chair, with the retiring president, Mr. J. Basil Hall, principal guest, on his right. Among those present were Sir William B. Leishman, director of the Army Medical Service; Vice Marshal D. Munro, director, Royal Air Force Medical Service; Sir St. Clair Thompson, president, Royal Society of Medicine; Miss Ivens, president, Medical Women's Federation; Sir Frederick N. Mott, president, Medico-Psychologic Association; Dr. George F. Buchan, president, Society of Medical Officers of Health; Mr. P. S. Roswell, president, Pharmaceutical Society, and Mr. J. H. Badcock, president, British Dental Association.

Beriberi Increasing in Japan.—According to the *Japan Medical World*, beriberi seems to be increasing in the Japanese army and navy. Official statistics covering the ten years ending in 1923 show that the number of cases of beriberi in the army in 1914 was 3.43 per thousand, and in 1923 10.47. The number of deaths per thousand in 1914 was 5.85; in 1923 it was 0.94. The number of beriberi patients in the navy in 1914 was 1.36 per thousand and 2.40 in 1923. These figures are small, compared with the incidence of beriberi from 1878 to 1883, when it was from 230 to 390 patients per thousand in the navy. The combined diet of rice and barley was adopted by the navy in 1886 and in the army in 1919. A society for the investigation of beriberi has been organized in Tokyo at the instance of Dr. T. Irisawa, former dean of the Imperial University Medical College, which will hold two general meetings a year. Communications to the committee should be addressed to the society at the Tokyo Imperial University Medical Department, Tokyo.

Personal.—Prof. Rudolf Kraus has been made president of the newly founded Vienna Society for Microbiology.——Subscriptions are being collected for the purpose of presenting a medal to Professor Mauclaire, Paris, on his approaching retirement from the Pitié. A bronze replica of the medal will be given for each subscription of 50 francs or more. The treasurer of the fund is M. Arnette, 3 rue Casimir-Delavigne, Paris.——The *Presse médicale* mentions the departure for the United States and Canada of Dr. J. Forestier, Aix les Bains, who has been invited by the American Radiologic Association to deliver a course of lectures on the work he has done with Dr. Sicard on iodized oil.——Dr. H. Hartmann has been reelected president of the A. D. R. M. (Association pour le développement des relations médicales) at Paris. He reports great progress in establishing postgraduate courses, and arranging for interchange of professors with other countries.——Dr. L. M. Pierra, 12 rue de Babylone, Paris, is the secretary of the international congress of the medical press of Latin nations, to meet at Paris in 1926. The main topics to be discussed are unification of terms and bibliography, rights in literary property, and the work of the medical press in organizing and reporting medical congresses.——The prize of the Marcel Benoist endowment, Zurich, has been awarded this year to Prof. H. Zangger, director of the medicolegal institute, Zurich, for his recently published work "Vergiftungen" (Poisonings).

Deaths in Other Countries

Dr. George Reid, formerly president of the Society of Medical Officers of Health and president of the Section of Medical Sociology of the British Medical Association, at Stafford, November 6, aged 70.

Foreign Letters

LONDON

(*From Our Regular Correspondent*)

Nov. 21, 1925.

The Health of School Children

Sir George Newman, chief medical officer of the board of education, has issued his report for 1924. Of about 1,500,000 school children inspected during the year in areas other than London, 20 per cent. were found to require medical treatment in some form, and a large number of others were found with defects which necessitated their being kept under observation. Considerable space is devoted to the health of the rural child, which is less satisfactory than that of the town child. It is pointed out that children cannot grow if their food is only bread and butter and tea, if their bodies are not rightly exercised, and if they live in cold and stuffy homes and schools. Among reforms advocated are that children under 6 should be discouraged from school attendance if the distance from school is excessive (or in winter during inclement weather); a sufficient midday meal should be secured for the child who cannot return home for it; facilities for the changing and drying of wet boots and clothing should be available in every rural school; insanitary rural schools should be made sanitary, and voluntary workers should be enlisted to organize education in mothercraft, domestic economy and child nurture and management, regarding which there is much ignorance and some neglect. The following table, which related to London, affords an idea of the incidence per thousand children inspected, of the various diseases of school children:

	1923	*1924*
Defective vision	62	62
Nose and throat disease	43	51
Ear disease	10	11
Lung disease (nontuberculous)	9	12
Skin disease	13	13
Squint	8	9
Eye disease	8	9
Anemia	8	9
Deformities	4	7
Defective hearing	5	6

In ten years the mortality among children from pulmonary tuberculosis has fallen by about 46 per cent., and from nonpulmonary tuberculosis by about 42 per cent., while the number of new cases of both forms has substantially diminished. When compared with the statistics for the population of all ages, these figures indicate that children offer a particularly hopeful field for specific antituberculosis measures and that a substantial measure of success, partly attributable to such measures, has already been obtained.

The Health of London

The report of the health officer for London, Sir William Hamer, for 1924, has just been issued. The death rate was 12.2 per thousand, which is slightly higher than in 1923, when the rate was 11.4, the lowest ever recorded. The infant mortality was 69 per thousand births, as compared with 61 in 1923, the latter being also a record year in this respect. The small rise in the death rate may be attributed to the prevalence of measles early in 1924 and to a slight increase in the deaths from influenza, bronchitis and pneumonia. The mortality from diarrhea and enteritis was lower than in 1923. The registrar-general estimates the total population of the administrative county of London in the middle of 1924 at 4,586,000. The births in 1924 numbered 85,147, being 6,515 fewer than in 1923. The birth rate was 18.6 per thousand, as compared with 20.1 in 1923 and 20 in 1922. During the last four years the number of births in London has declined by about 4,800 yearly. The rate has fallen continuously during the last fifty years at a rate of decrease of about 1.42 per thousand of population every five years. In the same period the marriage rate has remained much the same. There would have been a considerable decrease in the marriage rate but for the large increase of marriage during the war years. The decline in the marriage rate during 1921-1925 is too small to have played more than a negligible part in the concurrent fall of the birth rate. The decline in vaccination is such that Sir William Hamer considers the time not far distant when a serious epidemic can no longer be prevented. Deaths from cancer totaled 6,483, compared with 6,346 in 1923.

Links Between Mind and Matter

Sir Oliver Lodge, F.R.S., delivered the first of a series of lectures established by the British Science Guild as means of directing the attention of the public to the influence of science on human progress. Sir Oliver Lodge is the most striking example in this country of an eminent physicist who believes in psychic phenomena. His subject was "The Link Between Mind and Matter." He explained that he meant the impenetrable uniting ingredient or cosmic unit, which connected the otherwise dissociated or dissevered atoms of matter and enabled them to act on one another, even from a distance. This ingredient was essentially radiation—a disturbance in the ether or in space which traveled at one absolute velocity, which journeyed without loss or dissipation of energy, and which produced even at enormous distances its singular and striking results. "We are down among the foundation stones of reality," he said, "the laws which make matter possible, the laws which perpetuate the atoms of which our own bodies are composed. There are those who think that these material bodies represent ourselves, our personality, our memory and our character. If they can work out things on that hypothesis, by all means let them do so. But let them take the whole of the facts into account. The atoms are not isolated, and we are not isolated. Shall there be a link between atom and atom and not between mind and matter? The link may perhaps be traced through some further developments of physics. We are only beginning to understand the way in which matter acts on matter. We have not yet brought mind into the scheme. There must be a link between mind and matter and mind, and a corresponding link between mind and matter; for undoubtedly they do interact. There may be a link between mind and mind apart from matter. I think there is, but we are entering the region of speculation. Until we take the ether or radiation into account, our categories are incomplete." Sir Oliver Lodge concluded: "We cannot be satisfied with matter alone. We are bound to have a link between matter and matter, and if we keep our eyes open we shall find many other links, some of them suspected, some unsuspected."

Light for Animals in the Zoological Gardens

In a previous letter (The Journal, October 31, p. 1412), the provision of ultraviolet rays for monkeys by means of quartz globes in connection with electric light and the use of vita glass, which is transparent to the ultraviolet rays of the sun, was described. As this is a new field for the application of light therapy, some further information will be of interest. In the new reptile house to be erected at the London Zoo, modern devices for the variable heating of the cages, ventilation and drainage will be used. The roof lights, by which daylight will shine directly on the reptiles, are to be of vita glass, and there will be full provision for artificial sunlight from quartz incandescent lamps or a similar electric plant. Already in a temporary installation in the tortoise house, it has been found that iguanas, which mope in winter, even if kept sufficiently warm, respond at once to the light of quartz globes, and the most efficient plant to secure similar results will be designed. Dr. Leonard Hill, director of the department of applied physiology and hygiene of the Medical Research Committee, whose work on light therapy is well known, advised during the planning of the experimental monkey house and has promised to assist with the lighting designs of the reptile house. In the lion house a new roof with vita glass lights and an improved system of ventilation are being installed.

The General Medical Council

The General Medical Council has recently been the subject of abuse from the supporters of osteopaths and other irregular pretenders to the healing art, including many well known men, such as Bernard Shaw. Because in the course of its duties it has to do such things as remove from the register an anesthetist for working with an unqualified bonesetter, it is charged with being actuated by selfish trade-unionism. The president, Sir Donald Macalister, in opening the one hundred and twenty-second session, therefore fitly described the function of the council as prescribed by law. He pointed out that the council was a public department with judicial functions defined by statute and by the courts, working under the privy council and subject to supersession by the privy council if it defaulted. It was not vested with any power or duties for the protection of the medical profession other than those implied in the medical act of 1858; namely, "That persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." For that purpose, obviously a purpose of public utility, the Medical Register was set up. The council's duty to the public was simply to insure that no one who was not legally qualified by adequate professional training and testing should get on the register, and that no one who by his conduct had forfeited his claim to be entrusted with the status of a legally qualified practitioner should remain on it. The legal privileges of the qualified practitioner, as compared with the unqualified, were few. He had no monopoly of practice, such as the law conferred on dentists and midwives in their specialties. The privileges were rather trusts than advantages. Thus, only the qualified could legally grant a valid medical certificate of illness or death, or legally prescribe a dangerous drug. These privileges were clearly based on the assumption that members of the profession might be trusted to deal honorably with the public. Whoever, therefore, abused that trust by misusing the privileges his status conferred, or by covertly enabling others for gain to elude their legal disabilities, was chargeable with misconduct "in a professional respect," and made himself liable to the penalty of removal from the register. As the law stood, he was then as free to practice as if he had not been registered and the public was as free to employ him, if it thought fit. But the council had neither the power nor the responsibility of controlling his conduct thereafter. The council was frequently confounded with voluntary organizations and societies of physicians, constituted for scientific and professional purposes. But the Council had no professional interest to serve other than the efficient performance of its specific duties laid on it by law in furtherance of the public welfare.

The Practice of Osteopathy

That the craze of osteopathy recently introduced into this country has attained some popularity is shown by the fifth annual meeting of the council of the Osteopathic Clinic, at which it was declared that during the last twelve months 6,000 treatments had been given. Lord Deehurst, speaking of the attitude of the controlling bodies of the medical profession against legislation sought by "qualified osteopaths," said that the Medical Council did not want osteopaths to be recognized because physicians could not practice osteopathy themselves, not having the necessary qualifications. They wanted osteopaths to take medical degrees first and even then would not give any guarantee that they would recognize the work of osteopaths. It would help osteopaths if they could call in the services of anesthetists and medical specialists. He could vouch for several cases which had been cured by osteopathy after having been given up by physicians.

Kleptomania

M. Antheaume's attitude toward kleptomania is that kleptomania does not exist. So-called kleptomaniacs (mostly women) are in reality only common, ordinary thieves, in whose favor a plea of irresistible impulse is set up if they happen to belong to the well-to-do classes of society. Kleptomania should be eliminated from psychiatric nosology and should cease to be considered a valid excuse for an ordinary misdemeanor. It goes without saying that we must distinguish from so-called kleptomania the impulses to steal that may be presented by certain evident psychopaths, imbeciles, epileptics, and persons suffering from general paralysis or various forms of delirium. Before the Société de médecine légale, several other psychiatrists stated that they had never discovered any authentic cases of an irresistible impulse to steal.

So-called kleptomaniacs rarely operate in stores in which a strict watch is kept. They never seek to return of their own accord the stolen article. When they are finally caught, they never themselves invoke at first any pathologic defect as an excuse. That is always a secondary thought after their family or their lawyer has advised them to enter a plea of irresistible impulse. Antheaume proposes, as remedies: (1) mental prophylaxis through the organization in the large stores of Paris, by their initiative and at their own expense, of an effective perfectly apparent system of surveillance, which would leave pseudokleptomaniacs no hope of perpetrating a theft without being discovered; (2) intimidation of culprits by immediate arrest and conviction with suspension of sentence for the first offense, with or without the opinion of a psychiatric expert; (3) conviction and execution of the sentence in case of recurrence; (4) in certain cases in which it seems justified, the publication of convictions in the public press.

A Novel Source of Lead Poisoning

M. Bodron, public health commissioner in Brest, has published in the *Presse médicale* an article on a novel source of lead poisoning. Last April, the bureau of public health of Brest was faced with an epidemic of lead poisoning, the cause or source of which was unknown. The thirty-two patients, with three exceptions, all lived in the same section of the city (port de commerce), and inquiry brought out that all bought their bread of the same baker, and three persons employed in the bakery had been ill. The evidence pointed, therefore, to the bakery as the source of the intoxication. Examination of the sewer connections and of the water from the boiler or caldron gave a negative result. It was discovered, however, that the baker was using to heat his oven (a direct heating system) wood that had been obtained by breaking up old boats. Examination of the wood revealed that it was covered with paint that was rich in lead salts. The origin and the cause of the epidemic were thus demonstrated. In further substantiation, it was learned that the three patients who did not reside in the affected district were in the habit of eating bread that came from the incriminated bakery. In view of these facts, the mayor of Brest issued a decree, which was countersigned by the prefect of the department of Finistère, prohibiting within the limits of the commune of Brest the use of wood of demolished ships for baking. Legislation against the use, for baking, of wood derived from old boats is, however, not entirely new, for there were two ordinances dealing with the subject, issued in the department of the Seine, dated 1877 and 1898, respectively. The council of public health of the Seine has on several occasions, notably in 1914, rejected demands coming from dealers that the ordinance of 1898 be repealed. The council persists in refusing to permit the use, for baking, of "demolition wood," of whatever kind or origin. The oven used by the baker in question was heated by the direct heating system, but ovens with indirect heating systems are also dangerous when painted wood is used, by reason of the volatility of the lead salts and the readiness with which they become reduced to metallic dust under the action of charcoal. These vapors condense rapidly on the cold surface of the dough just as it is put into the oven.

Oleothorax

In a recent communication to the Academy of Medicine, G. Küss referred to the value of the method of oleothorax, as recommended by M. Bernou, in the treatment of pulmonary tuberculosis by artificial pneumothorax. Küss gave the precise indications for the use of oleothorax. It is advantageous during certain pleural effusions which so frequently complicate artificial pneumothorax. Oleothorax diminishes considerably the harmful effects of these effusions and facilitates their cure. It prevents annihilation of the partial pneumothorax in certain cases wherein continuance of this treatment is desirable. Furthermore, it makes possible permanent and effective compression of certain dense lesions that would resist compression by air or gas. Küss has invented a safe device for production of oleothorax. This device, which he presented recently before the Société d'études scientifiques de la tuberculose, has, among other advantages, that of permitting the measurement of intrathoracic pressure of the liquid petrolatum introduced. Küss holds that oleothorax deserves to be used more widely in phthisiologic practice.

ITALY

Oct. 30, 1925.

The Angelo Mosso Institute on Mount Rosa

The Angelo Mosso Institute, established on Mount Rosa, at an elevation of 3,000 meters above sea level and maintained for research on the physiologic effects of mountain regions, resumed operations in July. The institute has established a branch investigating center at the Margherita Lodge, which is 4,559 meters above sea level. The director of the institute, Dr. Amedeo Herlizka, professor of physiology in the University of Turin, is making a special study on solar radiation in high regions. Research students gathered here include Professor Morpurgo, who is investigating the effects of high altitudes on breathing; Professor Azzi, who is studying the phagocytic capacity of the blood in fatigue; Dr. Verdina, who is investigating the blood serum of fatigued persons from the immunologic point of view, and Dr. Arnaudi of the Serologic Institute of Milan, who is giving especial attention to the anaerobic bacterial flora of Monte Rosa. Among the foreign investigators may be mentioned Dr. E. Hung of Buenos Aires, who is conducting researches on the permeability of the skin of the frog, and Dr. H. Melchior of Berlin, who is pursuing botanic studies.

Interest of North and South America in Medical Studies in Italy

The University of Florence has received from Argentina 50,000 liras collected by Professor Dessy. The interest is to be used as the Guido Banti prize for researches in pathologic anatomy.

Prof. Aurelio Bianchi has sent 10,000 liras from Buenos Aires. The gift was sent to Professor Silvestrini, director of the clinic of internal medicine at the University of Perugia, and is to constitute a prize for the best research on phonendoscopy, to be presented to the university before June, 1926.

The Rockefeller Foundation is about to establish in Italian institutions a number of graduate fellowships in biologic or clinical subjects. Each student will be allowed 1,000 liras per month. The fellowships will extend to 1928. Appointments are for one year but are renewable for a second year. From those students who are successful in their researches, a number will be selected to pursue courses in other countries.

The First International Congress on Malaria

The first International Congress on Malaria, referred to in a previous letter, was held at Rome, October 4-6. The United States was represented by Dr. Hugh S. Cumming, Surgeon General and head of the U. S. Public Health Service; Colonel Russell of the Rockefeller Foundation; Drs. Hackett, McCallum, Thayer, King and Barber; Professors Strong, Bass, Fricks, Deeks, and others. The delegates from France were Drs. Brumpt, Lasnet, Marchoux, Mesnil and Sergent. The British representatives were Drs. James and Dale. Germany was represented by Professor Nocht; Belgium and its colonies, by Drs. van Campenhout and Broden; Brazil, by Dr. Humberto Gotuzzo; Colombia, by Dr. Luis Cuervo Marquez; Egypt, by Dr. Ahmed Bey Helmi; Hongkong, by Dr. McKenny, and the Netherlands by Dr. N. H. Swellengrebel. Dr. Reichmann, chairman of the health section of the League of Nations, was also present. The Italian delegation consisted of Senators Marchiafava and Sanarelli; Professors Ascoli, Bignami, Dionisi, Gosio, Sella, Bastianelli, Nazario, Alessandrini, Gualdi and Messea, and others. The government was represented by Mussolini, Federzoni, Suardo, the prefect of Rome, the royal commissioner of Rome (Senator Cremonesi), and others.

Dr. Massimo Sella of Rovigno discussed the results of anti-anopheles prophylaxis by the use of top minnows (*Gambusia*), imported from the United States, which destroy the larvae of the anopheles mosquito. Communications were presented by Professors Ghiron, Fontano, Neri, H. Durk (Germany), Bignami, Bastianelli and Monti. Professor Schilling spoke on the "Interpretation of the Significance of Biologic Conditions in the Blood of Malarial Patients," and papers were presented by Professors Etienne, Sergent, James, Brodel, Bentley, Nocht, Sadi de Bonen and Marzinowsky.

Professor Perez of Argentina proposed that an international institute against malaria be established in Rome, under the patronage of Italy, but with the aid of all nations, and that the first meeting be held in 1928. The Italian government accepted the proposal, and invited the concurrence of other governments interested.

Membership in the Royal Academy of Lynxes

At the recent election held at the Royal Academy of Lynxes, the following nationalists were chosen as members: Aldo Perroncito, professor of pathology at the University of Pavia, and Luigi Sabbatani, professor of pharmacophysiology at the University of Padua. As foreign members were elected: Lodovico Aschoff, Frederico Küster and Enrico Lebesgue.

Competitive Prizes Offered by a Scientific Academy

At the annual session of the Accademia dei Lincei, two new prizes in the field of vocational training and guidance were announced. Both prizes were established in the name of Gustavo Ragnoli and consist in gold medals valued at 5,000 liras each. The funds were furnished by the Istituto d'igiene, previdenza e assistenza sociale. One prize will be awarded to the commune, learned society or individual who presents the best bio-anthropologic study of a group of at least fifty elementary or grammar school pupils. This study must extend over a period of at least one year, and will be directed toward evaluating the physical and mental qualities of the pupils from the point of view of vocational guidance. The other prize will be bestowed on the economic or industrial society or on the indivdual that shall establish either directly or in cooperation with specialists a medical service for the selection of workmen, especially apprentices, on the basis of their physical and mental aptitudes. Competitors will be given two years in which to complete their work.

Modifications in the School Reforms Instituted by Ex-Minister Gentile

As previously mentioned, the minister of public instruction, Senator Gentile, established, among other things, the state examination for promotion in school and also for securing the right to practice a given profession after a school diploma has been obtained. While the desire to raise the standards of education met with approval, in a general way, there were criticisms of many of the details of the reforms. Senator Fedele, the present minister of public instruction, has modified some of the most bitterly opposed innovations, especially with reference to higher instruction. For example, assistants in universities may be transferred from one institutoin to another without reexamination. University competitive examinations will be open to all. The board of examiners, the makeup of which has been changed, will select three competitors who are capable of filling the chair. The faculty in which there is a vacancy will then select from the three candidates the future incumbent. Half of the superior council will be elected by the professors and half chosen by the minister of public instruction. On expiration of the terms of half of the present members of the superior council, their successors will be chosen by the professors.

Hygienic Propaganda Disseminated by Means of the Radiotelephone

The Unione radiofonica of Rome has broadcast a series of short lectures by Dr. Giovanni Pugliese on medicine and hygiene. One of the first subjects was "Errors and Preconceived Ideas on Tuberculosis." Briefly, the speaker explained tuberculous contagion and prophylaxis, emphasizing protection of children, the educative value of the sanatorium and the dispensary, and the absurdity of opposition to these beneficent institutions.

The Sanitary Council in the Colony of Eritrea

By a recent decree, the governor of the Italian colony of Eritrea on the Red Sea has created a medical council to deal with sanitary and hygienic matters. The sanitary council must keep the governor informed of health conditions in the colony and of the functioning of the various health services. It must present to the governor proposals as to the best hygienic and prophylactic measures to combat infectious diseases, and also submit suggestions with regard to the sanitary service. Dr. Ritucci, major in the army medical corps, has been appointed chief public health officer.

The New President of the Italian Red Cross Society

Senator Giovanni Ciraolo, for the last ten years president of the Italian Red Cross Society, has asked Prime Minister Mussolini to accept his resignation in order that he may devote all his time and energy to his project of an international league of public aid societies. Mussolini has accepted the resignation, at the same time appointing Senator Ciraolo a delegate to the League of Nations. The Marquis Carlo Centurione Scotto has already been inducted into office as the new president of the society.

BUDAPEST

Nov. 7, 1925.

The Modern Surgical Treatment of Pulmonary Tuberculosis

Dr. Nicholaus Roth, assistant at the university clinic, lectured before the Royal Medical Society on the modern surgical treatment of pulmonary tuberculosis. He said that this is the most important chapter in the progress of the medical sciences. A patient regarded as lost, not so long ago, can now be saved by surgical intervention. To be sure, the proper selection of cases requires great experience. The principle of surgical treatment is to place the sick lung at absolute or relative rest. Experience showed that tuberculous joints healed when put out of action. Experiments with immobilization of the sick lung were based on this assumption. Collapse therapy—this is the generally accepted term for it—may be total or partial. Collapse promotes cicatrization. The walls of cavities collapse if they are not exceedingly rigid, and if they are not fixed by adhesions to the parietal pleura. In the collapsed lung, circulation of blood and lymph is checked. In consequence of this the toxins and germs remain in loco. Thus can detoxication and the beginning of cicatrization be explained.

Surgical treatment is applied in three main ways: (1) artificial pneumothorax; (2) section of the phrenic nerve, and (3) extrapleural thoracoplasty. These can be performed independently or can be combined.

Indications for artificial pneumothorax are the following: (1) Severe, one-sided cirrhotic processes without adhesions. The prognosis of these cases is good. (2) Severe, one-sided, acinous, exudative and lobular caseous processes. The prognosis of these is less favorable than that of the former. (3) Moderately severe, progressive exudative processes. (4) Persistent hemorrhages.

Contraindications: (1) Extensive changes in the other side. It is well-nigh impossible to adhere strictly to this provision, because rarely is the other side entirely sound, and in some of these cases pneumothorax is indicated on relative grounds. For example, if partial collapse of the worse lung does not excite activity in the other side, complete collapse may be brought about. Thus successful procedures are described in the literature in which alternate compression was practiced. (2) Cases of caseous pneumonia. These are unsuitable for pneumothorax because the infiltrated tissues are unable to contract. (3) Other contraindications are extensive pleural adhesions of the other lung, chronic bronchiectasis, bronchitis, emphysema, asthma, rigidity of the chest, decompensated heart disease, intestinal tuberculosis, spondylitis, nephritis, nephrosis and diabetes. A frequent complication of artificial pneumothorax even if performed with the greatest precaution is a pleuritic exudative process. Some authors say, however, that exudates promote immobilization, and probably they do stimulate cicatrization. An undoubted disadvantage of pneumothorax is its excessive duration; on an average, two years. This, however, is not of great moment in cities, where patients may call on their physicians. Pneumothorax therapy has come to occupy its deserved place in our fight against tuberculosis. The initial exaggerations have entirely ceased.

By section of the phrenic nerve on one side the corresponding half of the diaphragm is paralyzed; the cone of the diaphragm forces itself into the pleural cavity and partially compresses the lung, chiefly the lower lobe. The section must be repeated several times, because the cut ends of the nerve grow together in a relatively short time. To do away with this, a portion of the distal part of the nerve is removed. The incision is made at the outer edge of the sternocleido-mastoid muscle, close to its lower attachment. It is not easy to find the delicate, thin nerve, superimposed on the scalenus muscle. Roth has seen the phrenic nerve confounded with a piece of fascia and has seen injury of the jugularis.

Indications for section of the phrenic nerve are as follows: (1) Circumscribed tuberculosis of the lower lobe. (2) Severe, moderately progressive, feverish processes, involving mostly one side and in which pneumothorax was not feasible because of adhesions. (3) Advanced processes involving both sides. Patients so affected cannot be cured, but their condition can be alleviated and, as Brunner says, it would be regrettable not to improve the patient's condition by an operation which, in general, is so harmless. (4) The most extensive field for phrenicotomy is severe, less progressive, subfebrile, exudative tuberculosis confined mostly to one side and in which pneumothorax has failed. If the patients feel better after this operation, thoracoplasty, in addition, is to be recommended. (5) It may be performed as an adjuvant to thoracoplasty, in cases of productive, cirrhotic, cavernous phthisis, the elimination of abdominal breathing promoting lung rest. (6) In cases of cirrhotic tuberculosis and pleural adhesions. If these lead to excessive contraction, the heart may be impaired in its function by the continuous dragging. The relaxation following paralysis of the diaphragm leads to cessation of this symptom. (7) It might be considered as life saving in cases of dangerous hemoptysis, in which pneumothorax cannot be performed. (8) In cases of artificial pneumothorax in which collapse of the lower lobe is impeded by fibrous adhesions. (9) As the completion of artificial pneumothorax, if there is no occasion for reinjection of gas.

Roth's experiences with this method lead him to conclude that phrenicotomy is a good measure, but we have to be very cautious not to transgress the limits of its indications. We must bear in mind that it cannot replace pneumothorax, and Roth would regard it an error to perform it in cases in which pneumothorax is possible. In one single instance he could justify this; namely, if, for financial reasons, the lengthy pneumothorax treatment is not practicable. We must not forget that pneumothorax, though admittedly of long duration, leaves no permanent traces, while the sequela of phrenicotomy, paralysis of the diaphragm, is irreparable.

The third surgical method is extrapleural thoracoplasty. This is a heroic operation, involving paravertebral resection of the tenth and eleventh ribs. Its indication is clear from what has been said. It is chiefly indicated in adhesive cirrhotic processes, but its relative indications, mentioned above, are not to be neglected. Roth has seen wholly hopeless cases become afebrile and patients regain capacity for work. All three methods that cause collapse may be combined.

Roth gives only a short sketch of this therapeutic method but it denotes a tremendous advance. The hygienic, dietetic, climatic, sanatorium treatment is pushed into the background. Our ideal is chemotherapy. Even this may be not very far distant.

Regulations on "Patent Medicines"

A regulation recently promulgated by the ministry of public health and sanitation requires that no person shall sell or offer for sale any "patent medicines" within the territory of Hungary until a full statement has been deposited with the minister of public health, showing the several ingredients contained in the medicine, and the quantity or proportion of such ingredients. At first it was proposed to make it compulsory to publish the composition on the label; but, owing to the opposition of certain manufacturing firms, this intention was, unfortunately, abandoned. Moreover, it is ordered that the label of every "patent medicine" containing poison shall be distinctly marked with words stating that fact. The penalty for breach of either regulation is a fine not exceeding ten million crowns; that is, about $150.

Marriages

Josias Benjamin Hibbetts, Jr., Nashville, Tenn., to Miss Miriam Burkloe Brown of Baltimore, September 29.

Samuel Fitzsimmons Ravenel, Greensboro, N. C., to Miss Katherine Parr Brown of Baltimore, September 29.

John Harvey Graff, Memphis, Tenn., to Miss Elna Lucie Rasmussen of Sidney, Mont., September 22.

Jabez North Jackson to Mrs. Florence Hinkle Storey, both of Kansas City, Mo., October 28.

Bruce L. Fleming, Philadelphia, to Miss Estelle Leedrop of Phillipsburg, N. J., in October.

Lindsay S. Milne to Miss Marian Young, both of Kansas City, Mo., December 15.

Harry S. Arkin, Chicago, to Miss Irene H. Kraus of New York, November 18.

Deaths

Nathan Edwin Brill ⊕ New York; Medical Department of the University of the city of New York, 1880; professor of clinical medicine, Columbia University College of Physicians and Surgeons since 1910; member of the Association of American Physicians, the American Neurological Association, the New York Neurological Society, the American Psychopathological Association and the New York Pathological Society; on the staffs of the Hebrew Orphan Asylum and Mount Sinai Hospital; served during the World War; in 1910 discovered a form of typhus fever known as Brill's disease; aged 65; died, December 13, following a long illness.

Gershom Hyde Hill ⊕ Des Moines; Rush Medical College, Chicago, 1874; lecturer on insanity, State University of Iowa College of Medicine, 1890-1906; professor of mental diseases, Drake University College of Medicines, Des Moines, 1903-1913; member of the American Psychiatric Association; assistant physician, 1874-1881, superintendent, 1881-1902, Independence (Iowa) Hospital for Insane; formerly on the staffs of the Congregational, Mercy and Methodist hospitals, where he died, November 24, aged 79.

J. Matt Gordon ⊕ Weatherford, Okla.; Medical Department of the University of Illinois, Chicago, 1905; president of the Custer County Medical Society; for many years chairman of the board of education; served in the M. C., U. S. Army, with the rank of captain, during the World War; aged 60; died, November 26, of nephritis.

Harry Ernest McCall, St. Louis; State University of Iowa College of Medicine, Iowa City, 1903; member of the Iowa State Medical Society; past president of the Taylor County (Iowa) Medical Society; served during the World War; aged 50; died, November 23, of angina pectoris.

Thomas Dunn Hutton, Glade Spring, Va.; Medical College of Virginia, Richmond, 1894; member of the Medical Society of Virginia; for many years secretary of the Washington County Board of Health; aged 56; died, November 19, of heart disease.

Earle Worthington Weathers, Elkton, Ky.; Louisville Medical College, 1905; member of the Kentucky State Medical Association; mayor of Elkton; aged 43; died, November 21, at a hospital in Hopkinsville, of injuries received in an automobile accident.

Henry Rutherford Morrison, Rockbridge Baths, Va.; University of Virginia Department of Medicine, Charlottesville, 1887; member of the Medical Society of Virginia; aged 60; died, November 11, in a hospital at Richmond.

William J. Ragan, Shawano, Wis.; Milwaukee Medical College, 1898; member of the State Medical Society of Wisconsin; aged 59; died, November 27, at St. Mary's Hospital, Milwaukee, following an operation.

Albert Evans Tatman, Eureka Springs, Ark.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1904; veteran of the Spanish-American and World wars; aged 55; died, November 24, of heart disease.

Henry Granville Godfrey ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1900; formerly assistant demonstrator of clinical medicine at his alma mater; aged 50; died, October 27, of heart disease.

Byron Ernest Finley, St. Louis; Kentucky School of Medicine, Louisville, 1897; member of the Missouri State Medical Association; aged 49; died, August 15, at Los Angeles, of chronic nephritis.

William H. Dewing, Clayville, N. Y.; Hahnemann Medical College of Philadelphia, 1882; for many years health officer of Clayville; aged 67; died, November 24, at the home of his son in Scotia.

Charles E. Rowe ⊕ Hubbell, Mich.; Northwestern University Medical School, Chicago, 1905; past president of the Houghton County Medical Society; aged 49; died, November 24, of septicemia.

Christian Lenker ⊕ Schuylkill Haven, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1877; Civil War veteran; aged 83; died, in November, of heart disease and senility.

Caroline North Stevens, West Cornwall, Conn.; Tufts College Medical School, Boston, 1898; member of the Connecticut State Medical Society; aged 51; died recently, of pulmonary embolism.

Reinhart F. Schwartz, Charlotte, Iowa; Medical Department of the University of Illinois, Chicago, 1906; member of the Iowa State Medical Society; aged 42; died, November 22, at Clinton.

Perry Hardy Doughty, Juneau, Wis.; Keokuk (Iowa) Medical College, 1892; member of the State Medical Society of Wisconsin; aged 57; died, November 21, following a long illness.

Thomas Francis Darby, River Point, R. I.; Baltimore Medical College, 1898; member of the Rhode Island Medical Society; aged 50; died, November 23, of heart disease.

George P. Knight, Monticello, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1876; county health physician; aged 72; died suddenly, November 24, of heart disease.

John W. Knox, Stewardson, Ill.; Medical College of Ohio, Cincinnati, 1873; served as postmaster, 1872-1885; formerly a druggist; aged 90; died, November 20.

George Gunn, San Francisco; California Eclectic Medical College, Los Angeles, 1893; aged 62; died, November 24, of ruptured aneurysm of the aorta.

Benjamin Franklin Tichenor, Crescent City, Fla.; Kentucky School of Medicine, Louisville, 1891; aged 59; died, November 18, of angina pectoris.

Wilfred Ellsworth Rounseville ⊕ Attleboro, Mass.; Medical School of Harvard University, Boston, 1909; aged 43; died suddenly, in November.

Clifton Mears Rosin ⊕ New York; Bennett College of Eclectic Medicine and Surgery, 1907; aged 41; died, November 24, at Philadelphia.

Carr Warder Newman, Hinton, Mo.; Kentucky School of Medicine, Louisville, 1894; aged 65; died, in November, of cerebral hemorrhage.

Andrew J. Campbell, Elizabethtown, Tenn.; University of Tennessee College of Medicine, Memphis, 1892; aged 69; died, October 5.

David J. Roberts, New Rochelle, N. Y.; New York Homeopathic Medical College and Hospital, 1886; aged 69; died, November 23.

Edward C. Cartledge, Atlanta, Ga.; Atlanta Medical College, 1895; aged 58; died, November 28, following a long illness.

James M. Wheat, Coker, Ala.; University of Nashville (Tenn.) Medical Department, 1907; aged 52; died, November 20.

Alberta Reed Carpenter, Hustonville, Ky.; Woman's Medical College of Cincinnati, 1895; aged 58; died, November 2.

Franklin Maynard Eaton, Calais, Maine; Medical School of Harvard University, Boston, 1885; aged 64; November 22.

William Corpron, Yakima, Wash.; University of Michigan Medical School, Ann Arbor, 1891; aged 61; died, October 24.

Frank D. Soverin, Braceville, Ohio; Toledo Medical College, 1891; aged 64; died, October 3, following a long illness.

Alice E. Loomis, Jefferson, Ohio; Cleveland University of Medicine and Surgery, 1890; aged 67; died, October 16.

Roderick L. Fraser, Victoria, B. C.; Jefferson Medical College of Philadelphia, 1891; aged 65; died, November 15.

Frank Allan Kinsey, Orange, Calif.; Missouri Medical College, St. Louis, 1898; aged 55; died, November 11.

William Charles Wall, Atlanta, Ga.; Louisville Medical College, 1894; aged 70; died, November 19.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

VITALAIT NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report. W. A. PUCKNER, Secretary.

"Vitalait" is the uninforming name under which the Vitalait Laboratory of Newton Centre, Mass., markets a culture of *B. acidophilus.* It is so named on the label, but no statement of the number of viable organisms contained in a given quantity of the culture is given.

In the advertising for Vitalait which is sent to physicians, the generally discarded autointoxication theories of Metchnikoff are used as a warrant for recommending its use in a host of conditions. On this basis, the booklet "Vitalait and Its Uses" gives sweeping recommendations for the use of the product. In autointoxication it is said that "there is no known therapeutic aid which can equal Vitalait"; in neurasthenia it is said that "the favorable results from Vitalait . . . have made it the 'first thought' of most physicians"; neuritis is said to be "one of the many conditions where Vitalait acts as if by magic." In general, Vitalait is said to be "the magic wand in the physician's hand." The booklet also states that Vitalait is of value indirectly in anemia, chlorosis, dropsy, dyspepsia, eclampsia, fevers, gastralgia, gastritis, headache, high blood pressure, influenza, insomnia, nephritis, obesity, obscure pains and typhoid fever.

A layman who wrote to the Vitalait Laboratory, Inc., of Newton Centre, Mass., for information received a letter signed "R. D. Turner, M.D., President." Enclosed with the letter were two pamphlets and an order blank. One pamphlet, entitled "Vitalait," with subheads, "What it is," "What it does and How it does it," explains:

> "Vitalait helps the system to get rid of poisons formed by the activities of the body cells."

Also:

> ". . . among the diseases caused by intestinal toxemia may be listed acne, anemia, arterio-sclerosis, arthritis, asthma, auto-intoxication, catarrh of the intestines, colitis, constipation, diarrhea, gastritis, gout, hay fever, headache, high blood pressure, influenza, insomnia, lumbago, migraine, muscular rheumatism, myalgia, neurasthenia, neuritis, obscure pains, skin diseases, etc."

The second pamphlet "Vitalait and its Uses" is plainly addressed to the public. It begins with a statement that the acquisition and maintenance of vigorous health depends on the normal functioning of every part of the human body and that this is governed by proper assimilation and the prompt and efficient elimination of waste products. It then expounds how waste material accumulates, how this accumulation is putrified by the bacteria eaten with the food, and how the poisons formed are carried to the various tissues "where they exert their deleterious influences." It is then said:

> "In the joints they cause arthritis, rheumatism, etc.; in the nerves, neuralgia and neuritis; in the blood vessels, arteriosclerosis or hardening; in the stomach, gastritis and indigestion; in the intestine, constipation or diarrhea; in the brain, headache, lassitude, etc.; in the muscles, pain or general weakness, and so on throughout the whole system."

After thus depicting the evil effects of "autointoxication," the pamphlet proceeds:

> "It is obvious that if a person could regularly put into his intestine the helpful *Bacillus acidophilus,* he could prevent the terrible poisoning caused by the harmful bacteria, or if the harmful ones had already obtained a foothold, he could restore them and permit his body to free itself of the accumulated poisons and regain its normal healthy state."

To this end, the Vitalait Laboratory of Newton Centre, Mass., offers to aid the reader in preventing or overcoming autointoxication by supplying him with the needed panacea, Vitalait.

Vitalait (Vitalait Laboratory of Newton Centre, Mass.) is unacceptable for New and Nonofficial Remedies because it is marketed under a noninforming name; because the claims made for it are unwarranted and misleading; and because it is exploited to the public in a way to lead not only to its use for imaginary ills, but also for conditions in which correct diagnosis and rational medical treatment are all important.

Correspondence

SERUM FOR INFANTILE PARALYSIS

To the Editor:—In a communication in THE JOURNAL, September 26 (page 995), Dr. George Draper makes certain points with which I must disagree. With one, however, the necessity for a preparalytic diagnosis to secure the best results in any form of serum treatment, all clinicians will heartily concur.

Dr. Draper favors the use of serum from patients recovered from acute poliomyelitis and cites a specific case in which, by the administration of such serum, a baby with infantile paralysis recovered without the onset of paralysis. He acknowledges that previous reports of the use of serum from recovered patients with poliomyelitis have not been encouraging, but attributes this to the giving of insufficient serum.

The proper dose, according to Dr. Draper, should be 15 c.c. intraspinally, with from 150 to 200 c.c. of serum intravenously, requiring about 500 c.c. of blood. He thinks that the blood might either be secured from recovered patients by health boards, or bought directly from the patients, if not given by them gratuitously.

Dr. Draper refers to Rosenow's serum only to condemn it. He states that nobody "has ever produced infantile paralysis in monkeys." In the (Mayo) *Clinic Bulletin* (Sept. 23. 1924), Rosenow is reported as reproducing in rabbits with remarkable verisimilitude the various types of human poliomyelitis by means of cultures of his pleomorphic streptococci taken from the nasopharynx of patients.

I have used Rosenow's antistreptococcic poliomyelitis serum for several years and consider it invaluable. Dr. Draper affirms that serum from recovered patients "is of no value if paralysis has already occurred." I do not agree with this statement at all with the use of Rosenow's serum, although the earlier it is given the better. Thus, within a few weeks an adult of 34 was seen in consultation in a distant town with great rigidity of the neck and back, severe headache and backache, muscular twitchings, fever and vomiting, all appearing within twenty-four hours. Rosenow's serum was sent but, before its arrival (twelve hours later), paresis had affected one leg and difficulty in swallowing occurred. Two doses of Rosenow's serum were given intravenously; the paresis disappeared in a day and the difficulty in swallowing within a few days, and the patient made a complete recovery. For the first time in the history of the small town in which the patient lived, three cases of infantile paralysis had occurred, and within a week. The case recorded is the only one in which the patient lived.

This brings up the manner of giving the serum. Dr. Draper affirms that the injection of a foreign serum intraspinally is a dangerous matter in increasing congestion of the cord in poliomyelitis and, as in the previous sentence he had been speaking of Dr. Rosenow's serum adversely, one would naturally infer that Dr. Rosenow's serum is given intraspinally. This is not the case, and Dr. Rosenow has repeatedly warned against its use in this way. His serum is injected intravenously or intramuscularly, a much easier method than intraspinally.

Dr. Draper, with his exceptional training, ability and experience recognizes the futility of his single case proving anything in respect to the therapeutic value of human serum, and so do I.

The case recorded will serve to offset Dr. Draper's, and it is difficult for us not to parade our apparent therapeutic successes.

Every clinician with much experience knows that in epidemics of infantile paralysis the majority of patients do not develop paralysis at all and recover spontaneously without any treatment whatever; that the paralysis may be naturally slight and rapidly disappear; that the degree of virulence and mortality vary in the most extraordinary manner in different outbreaks, and that the beneficial effect of lumbar puncture alone is sometimes surprising.

While I have not seen Dr. Rosenow's reproductions in animals of human poliomyelitis, I have observed and been amazed by the almost miraculous reproduction of epidemic encephalitis in rabbits by Rosenow with cultures of his green-producing streptococcus taken from patients. It is difficult, indeed, not to be greatly impressed by the marvelous mimicry of the various forms of the disease in man in their every detail.

To look at the matter in a practical way, what have we to aid us without the serum of Rosenow in epidemic encephalitis and acute anterior poliomyelitis? Human serum is not hyperimmune, as is Rosenow's, and its supply is and must be limited and, as in the case of serum from recovered influenza pneumonia patients, its curative effect is questionable (Peabody).

Kenelm Winslow, M.D., Seattle.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF TETANUS

To the Editor:—I have now under treatment a case of tetanus. I gave the patient 30,000 units of antitetanic serum intraspinally, the second day after the onset of the disease. At the same time I gave him 30,000 units intravenously. He began to improve rapidly, but still after five days his back muscles and jaws are firmly spastic. He feels well, and apparently is recovering, except for this contraction. Is it advisable to give him any further antitetanic treatment, in view of his rapid improvement, or shall I wait for this muscular rigidity gradually to subside?

M.D., Illinois.

Answer.—In persons recovering from tetanus, the rigidity of muscle groups subsides slowly, and therefore the persistence of rigidity for a number of days in a case such as that described, in which an adequate dose of antitetanic serum has been given, is not an indication for repetition of the serum.

A rational treatment of tetanus by antitoxin requires a clear understanding of the distribution of the tetanus toxin in the body of the patient. Following the receipt of the wound and the introduction of tetanus bacilli or spores, the production of tetanus toxin proceeds at a rapid or slow rate depending on whether the conditions of the wound are favorable or unfavorable for the growth of the bacilli.

As the toxin is formed, it is either absorbed by the motor end plates of nerves in the vicinity of the wound, or enters the lymphatics, to pass into the blood stream, and thence be absorbed by the motor end plates of nerves all over the body. The toxin travels centrad along the nerves at a fairly uniform rate, and consequently the toxin traveling along the shortest nerves first reaches the central ganglion cells, with resulting spasm in the muscles supplied by them. Trismus is therefore usually the earliest symptom of tetanus, with cervical rigidity following soon afterward, no matter where the location of the wound. In certain rare cases in which toxin production is very slow, and small in amount, rigidity of an extremity may precede trismus.

When the presence of tetanus is first recognized, the toxin is then already widely distributed in the body. The intravenous injection of one large dose of from 30,000 to 40,000 units of antitoxin will neutralize so far as is possible the toxin in the blood stream. The intrathecal injection of 10,000 units will neutralize, to some extent, toxin reaching the spinal cord.

If a fatal dose of toxin has not already reached the central nervous system and become inaccessible to neutralization by antitoxin, treatment by antitoxin will help to save life. Obviously, antitoxin should be given in adequate doses at the earliest possible moment after recognition of the disease. Symptomatic treatment by sedatives such as bromids and chloral, abundance of fluids and the maintenance of quiet surroundings are important. Magnesium sulphate given intrathecally or by intravenous injection to reduce nervous irritability are warmly advocated by some, and seem often to be of value. Their use requires great care to avoid overdepression, with interference with respiration.

MEAT AND PASTRY IN THE DIET—COD LIVER OIL

To the Editor:—1. There have been recently published in some of our most popular periodicals several autobiographic articles by people in the limelight explaining their methods of keeping fit. One of these never eats meat; another, only chicken or squab; a third, only white meat or fish. All avoid "red meat." Have we any scientific proof that a moderate serving of meat once a day is harmful to any undiseased person of whatever age? Another item frequently stressed is the elimination of all pastry from the diet. Is there any objection to a moderate amount of pastry if it does not crowd out other needed foods or if it is not added to an already sufficient number of calories? In other words, is it harmful in itself? 2. I recently heard a cooking teacher advise the use of a pinch of cayenne pepper in all meat and vegetable dishes because "it is a wonderful stimulant to digestion." Your opinion, please? 3. In the event of cod liver oil causing urticaria in an infant, what would you recommend?

M. D. M., M.D., Lima, Ohio.

Answer.—1. All these various apparently mutually contradictory methods have in common a restriction in diet. This leads to moderation in eating, which is the great desideratum. A moderate amount of meat once a day is not harmful, nor is there any objection to a reasonable indulgence in pastry.

2. The less spicing one can get along with, the better. Condiments and spices, it is true, stimulate digestion; but they also irritate the stomach, the liver and the kidneys; and there is a tendency to progressive increase in their use. People of vigorous digestion require little seasoning. Unfortunately, the time does come, as we get older, when we require a certain amount of seasoning to help along in digestion; and, used in moderation, it is more beneficial than harmful. If cayenne pepper stimulates appetite and digestion it may be used occasionally, but any stimulant becomes less efficient on continuous use.

3. If an infant has rickets and an idiosyncrasy against cod liver oil, actinotherapy in the form of sun baths or ultraviolet ray exposures should be employed. Cod liver oil extract and irradiated foods have not yet been developed to a sufficient extent to be commercially obtainable in reliable form.

LONG CONTINUED USE OF INSULIN

To the Editor:—Has the long continued use of insulin, even in mild dosage, any unfavorable tendency? On the other hand, has experience demonstrated any favorable effect to be expected? This refers to a patient, aged 68, who has had gangrene of one extremity, amputation and healing, although arteriosclerosis is quite markedly present.

P. W. V., M.D., Iowa.

Answer.—In Medicine Monographs, Volume 6, Insulin and Its Use in Diabetes, by J. J. R. Macleod and W. R. Campbell (Baltimore, Williams & Wilkins Company, 1925), the authors say that three years of insulin treatment of patients with severe diabetes, with a lack of any evidence of deleterious effects, is sufficient guarantee that insulin can be continuously used without its value becoming impaired by unforeseen occurrences.

"The insatiable hunger of the emaciated, undernourished diabetic patient disappears with the improved state of nutrition, and is replaced by a healthy appetite for regular meals. We have found that the menstrual function has returned in several instances; so also, occasionally, has sexual desire. Eyesight usually improves in those cases with lesser degrees of local damage. The restoration of physical vigor is such that most patients are able to return to work. Most interesting is the change in the mental state of the patient. From depression, melancholia, inability to think, and often black despair, patients recover to an astounding degree their mental alertness, cheerfulness and interest in their surroundings. Irritability and insomnia disappear. . . . Insulin provides for some patients an opportunity for resting the pancreatic function, which was impossible by other methods of treatment, and as a result increases in tolerance are not uncommonly observed . . . The proportion of patients with uncomplicated diabetes who find it possible to discontinue insulin after a time is comparatively small, but many show an increase in tolerance which, though small, is yet sufficient to render it possible to supply a working diet with the same dose of insulin as was previously necessary when only a basal maintenance diet could be given. In some cases the insulin dosage may even be reduced. It seems possible that this so-called recovery of tolerance which usually occurs in the first months after treatment with insulin should be regarded rather as release of a latent tolerance submerged by previous overwork of the pancreas.

"The question of an actual regeneration of islet tissue must be very cautiously approached. It can be settled only by time, and it seems unfair to arouse hopes that are not justified by experience. In some of the mild cases and particularly in the young this is a possibility. It may be pointed out that children who have not attained adult body weight present the additional possibility that, under careful treatment and rest of the pancreas with insulin, a normal growth of the pancreas with increase in age may occur and thereby a greater tolerance for carbohydrate may be acquired."

From pages 159 and 160, we quote:

"The aged patient generally shows a much less rapid recovery of strength, gains weight more slowly, and he requires a proportionately larger dose of insulin to produce a given amount of improvement. . . . Aged diabetic patients also suffer from many complications in part related to their age and also contributed to by the diabetic state. Coldness, numb extremities, muscle cramps, paresthesia, neuritis, ataxia, incoordination, etc., are dependent usually on permanent organic changes in the circulatory and nervous systems, and the possibilities of improvement under insulin are rather remote."

INTESTINAL INFLUENZA

To the Editor —Please prepare or have prepared an editorial or, in some way, give us your opinion, or the opinion of others, on this so-called intestinal influenza that we hear so much about in country practice. We have lately consulted several authorities on this supposed disease and can find no one man or set of men that will agree or even are willing to admit that there is such a disease I would appreciate much to have it answered fully or to leave it for open discussion and get the opinion of others on this subject.

C. J. SMITKAY, M D, Belle Plaine, Iowa

ANSWER —There is no reasonable doubt of the existence of an intestinal form of influenza which in certain pandemics has been noted to occur in a little more than 1 per cent. of all cases of the disease. Authoritative information on this subject may be found, for instance, in the volume on Influenza (Nothnagel's Practice, Philadelphia, W. B Saunders Company, 1905). Of course, diagnosticating intestinal influenza is quite likely to be erroneous in the absence of an epidemic. Until the etiologic factor of influenza has been isolated, we can make a positive diagnosis of the disease only from its epidemic or pandemic character.

INGROWN HAIRS AND PAINFUL SKIN

To the Editor.—I have a patient who has many ingrown hairs on his face, making it impossible for him to shave His skin has become tender and slightly edematous I have used various oils and ointments, electrolysis not being practical, as the ingrown hairs are too numerous and the skin too tender. This man is in business, and the condition is embarrassing, besides being painful. Kindly outline any treatment, besides that I have enumerated, or give me some ointment combination that I could prescribe. (Kindly omit name.)

M.D, Chicago

ANSWER.—Patients who think they have sore face from ingrowing hairs are usually mistaken. The trouble is usually not ingrowing hairs but arises from the fact that such patients keep the face sore either by digging for suspected ingrown hairs or by cutting off the conical points around the hairs in shaving. The course to pursue is, first to stop picking at the face; then, not to shave close; and, finally, to wash the face lightly after shaving and at night with a mildly astringent solution. For this purpose a solution of 8 per cent. aluminum acetate, 1 ounce (30 c c.), to a pint (475 c c.) of water may be recommended. But picking at the face must be stopped!

Book Notices

Infections of the Hand. A Guide to the Surgical Treatment of cute and Chronic Suppurative Processes in the Fingers, Hand, and orearm. By Allen B. Kanavel, M.D., Professor of Surgery, Northestern University Medical School. Fifth edition. Cloth. Price, $5.50. . 499, with 196 illustrations. Philadelphia: Lea & Febiger, 1925.

A surgeon is not justified in treating hand infections withut a thorough and intelligent study of this book. Now in its fth edition, it represents one of the most brilliant monoraphs in surgical literature. The author makes a detailed esentation of the anatomic relationships between such ructures as tendon sheaths and bursae, fascial spaces and mphatics. By means of dissections and experimental injecons of cadaver hands, he has demonstrated the routes of tension of pus from the common foci of infection. He has osely correlated clinical signs with underlying pathologic anges by a clear diagnostic picture of each type of infection. his has resulted in the establishment of early diagnosis, rticularly in the dangerous tendon sheath infections. He ints out the importance of properly placed incisions, callated not only to provide efficient drainage, but also to void unnecessary damage to the motor mechanism of the and. There is an excellent exposition of the lymphatic nfections. The first part of the work is devoted to simple calized infections, such as felon and paronychia; the second rt to grave infections, such as tendon sheath and fascial ace infections. The anatomy of the hand and forearm is udied from a surgical standpoint, and sections of the book eal with lymphatic and allied infections, erysipelas, gas acillus infections and tuberculosis. There are also chapters n the complications and sequelae of hand infections, such as nkylosis and contracture, with a study of corrective meaures. In the chapter on after-treatment, the author makes it bvious that the control of infection must be accomplished ithout the sacrifice of function; the so-called position of nction must be maintained from the start, and in old cases ust be obtained by the use of splints. The text is profusely lustrated.

A Synopsis of Surgery. By Ernest W. Hey Groves, M.S., M.D., .Sc., Surgeon to the Bristol General Hospital. Seventh edition. Cloth. rice, $5. Pp. 671, with 162 illustrations. New York: William Wood & o., 1925.

The author, in the preface, says: "It is, of course, obvious nat the large works cannot be dispensed with; but after a tudent has carefully read through a complete textbook, he nay find this synopsis will aid his memory in retaining a ast array of facts in an orderly manner." Obviously, such synopsis may tempt the student to take the short-cut and o dispense with the larger works altogether. The book neets its aim unusually well. The introduction of drawings nd diagrams in the new edition adds considerably to the alue of the text. The information throughout is thoroughly ıp to date with one glaring exception, which is to be found n the chapter on exophthalmic goiter. To quote: "Treatnent: Bromides, digitalis and belladonna are useful. Iodin, odides are harmful. Moebius' serum, from thyroidectomized nimals, is the most active remedy. Surgical: Arterial ligaure—both superior and one inferior arteries are tied and ome improvement results. Partial thyroidectomy: Removal of the whole of one lobe and half the opposite. There is danger of death from acute thyroid intoxication." The nformation contained here is not only inadequate; it is ncorrect. The use of iodin preliminary to the operation has robbed the latter of the danger of death from intoxication. It has taken the place of polar ligation and constitutes one of the most important advances in this field. The removal of "a whole one lobe and a half of the other" would not cure many cases. It is conceded by surgeons of experience that nothing short of a radical subtotal thyroidectomy is worth while. This emphasizes once more the danger of treating surgical subjects in synopsis form.

A Synopsis of Gynaecology. By Arthur Gray, F.R.C.S., M.R.C.P., Gynaecological Surgeon, Hampstead General Hospital. Cloth. Price, $3.75 net. Pp. 352. New York: Longmans, Green & Co., 1925.

Probably the great majority of men teaching in medical schools have at some time or other prepared, each one for himself, a sheaf of notes pertaining to his particular subject. These notes usually are in typewritten form, and each compiler has no doubt looked forward to the time when expansion into a formal textbook would become feasible. This author has been the first, so far as we know, to have such notes typed with printers' ink in book form. For this volume is just that—a printed notebook. Concise to the point of incomplete sentence construction, telegraphic in its brevity, the longer paragraphs reading like night letters, the pages are packed with concrete statements, as a result of which argument becomes didacticism. As a result, further, the fundamental principles of gynecology are emphasized, its elaboration and technic merely suggested. Far from being a fault, this is a relief, when held up in comparison with the usual textbook. In its brevity of statement, the volume covers the field of gynecology in all its phases. In its classification, it is more conventional; in this respect the typical textbook is followed. To the student in training, such an exposition would be of no value; and, indeed, it is not intended for the student. In his preface, the author states that the book is primarily meant for the instructor and for use in rapid review by those preparing for higher examinations. The details of operations have been purposely omitted, the greater emphasis being placed, properly enough, on pathology.

Midwifery Mechanics. By Lieut.-Colonel Andrew Buchanan, I.M.S., M.A., M.D. Cloth. Price, $2.50. Pp. 82, with 12 illustrations. New York: Oxford University Press, 1924.

Wisdom and technical experience are exhibited in this little book. The author elaborates the theory of "pivotal points," by which he means the apex of the maternal subpubic arch and the craniovertebral junction of the child. His thesis emphasizes the necessity for recognizing before labor the presentation and the attitude of the child and the effect which the distance of the pivotal points from each other, and the ease with which they may be brought into relation, will have on the progress of labor. In the course of his argument, he finds a need for employing the term "revolution" in place of "flexion or extension" to explain the anteroposterior movement of the head on its vertebral axis. In a mechanical sense the term might carry a greater accuracy, as he contends; but, on the other hand, flexion and extension have the authority of familiarity and long usage, as well as an analogy with a similar action in other joints. Again, the term "long axis of accommodation," which the author prefers, is really no improvement in nomenclature over "Pajot's law of accommodation," with which we have long been familiar. Whatever the name, the law applies equally to the head on the pelvic floor and the child in the uterus. That the back of the babe tends to turn forward in order to accommodate its convexity to the concavity of the anterior wall of the uterus, all will agree; but that this tendency is produced by the projection of the lumbar vertebrae of the mother rather than by the physiologic flatness of the posterior wall of the organ is not so clear, unless indeed the author means that those protruding vertebrae are factors in the etiology of the flattened posterior wall. In his mechanical exposition, the author stresses the fact that if the back is in front it will result in a good vertex or a bad face position, that is, with the chin posterior; while, if the abdomen is in front, a good face or a bad vertex position will occur. In concise form he states this as his "twelve letter formula," and urges the importance of locating the position of the child's back before labor. Such accuracy of examination cannot be emphasized too much, but in practice the procedure will be executed only by specialists or deeply interested students; and surely it will be neglected, if not despised, by the surgeon, the internist, the ophthalmologist and others who practice midwifery, not obstetrics, in off hours. It is true in general, as the author says, that the physician and widwife are imperfectly trained in obstetrics. It is perhaps true that many men in teaching positions are more interested in self-exploitation than in handing down the art of obstetrics or transmitting an enthusiasm for its study. It is *undoubtedly true also* that most cases of labor are conducted without any attempt in the prenatal period to learn what problem is presented by a given pregnancy. It is for this reason that Comyns Berkeley, in his discussion of occipitoposterior positions, is justified in saying that either the physician does not recognize the complication or, if he does, is usually ignorant of the correct way to handle it. For this reason too, Dr. Buchanan cries aloud for more skill, more care, more thought and more taking of pains in the conduct of pregnancy and labor. His book will strike a sympathetic chord in the hearts of the few who are really interested in and anxious for any thoughtful consideration of the mechanics of midwifery.

Die aesthetische Erscheinungsweise der Farben. Von G. J. von Allesch. Paper. Price 12 marks. Pp. 157. Berlin: Julius Springer, 1925.

This work appears to be based on a series of painstaking experiments carried on over a considerable period for the purpose of achieving something like a standardization of the emotional reactions caused by color and color combinations. The main difficulty encountered is the proper recording of these reactions. The persons used for the observations must record their impressions by describing them in words. The describing of the emotional experience of several listeners to a certain composition in music would be radically different. Compared with the presentation of formless colors, the description of a person's reaction to a musical composition would be definite. As a matter of fact, the divergence of reaction to colors as recorded in these experiments is so various and contradictory as to become practically meaningless from a scientific point of view. The esthetic conclusions that might be based on these observations would not be sufficiently well founded for the guidance of a producing artist. There may be some interest in applying the conceptions gained to the historical survey of the art of colors. The actual value of these experiments seems at this point of development in doubt.

Orthopädische Therapie. Bearbeitet von Prof. Dr. Hermann Gocht, Direktor, und Dr. Hans Debrunner, bisher Oberarzt der orthopädischen Universitatsklinik, Berlin. Paper. Price, 22 marks. Pp. 340, with 279 illustrations. Leipsic: F. C. W. Vogel, 1925.

This monograph deals exclusively with the treatment of orthopedic conditions. In large textbooks, methods of treatment are described at length seriatim, and the reader is left to determine which method of treatment should be instituted. This treatise attempts to assist the beginner by presenting only those methods which are in use and which have stood the test of time; in each chapter a scheme of treatment is given in detail. Conditions presenting similar pathologic findings and causes are grouped together. The authors believe that in this manner the therapeutic indications will be more easily understood. Among the topics discussed in the book are systemic diseases of the skeleton; inflammatory diseases of the bones and joints; deformities of the neck, vertebral column and pelvis; deformities of the long bones; deformities of the joints; paralyses due to diseases of the muscular apparatus, and diseases of the soft parts of the motor apparatus. The illustrations showing operative procedure were, almost without exception, sketched at the operating table, the salient points being particularly emphasized. In order properly to bring out the important facts, most of the illustrations are entirely new. The book shows great thought and care in its preparation and is a real addition to orthopedic literature. It can be warmly recommended.

Medicolegal

Action for Performing Unnecessary Operation

(White v. Hirshfield (Okla.), 236 Pac. R. 406)

The Supreme Court of Oklahoma, in reversing a judgment rendered for the defendant physician, says that the plaintiff alleged that, in addition to delivering her of a child by Cesarean section, the defendant, without her consent, performed on her the unnecessary operation of tying or removing the fallopian tubes. The question presented to the supreme court was whether the plaintiff's right of action was barred by the statute of limitations of Oklahoma, which requires an action for assault and battery to be commenced within one year; and it is held that it was not. It is held that, in an action for damages brought by a patient against a physician and surgeon for performing an unnecessary operation on the plaintiff, such operation being without the consent of the plaintiff, the plaintiff may waive the right of action for technical assault and battery and bring an action for injury to his person by reason of such acts constituting malpractice and a violation of duty as between the physician and the patient, and in such case the statute of limitations which fixes two years as the time in which an action for an injury to a person may be brought is applicable, and not the limitation of one year fixed by the statute for actions for assault and battery.

The supreme court is of the opinion that when a patient is under the care, treatment and control of a physician, and when an unnecessary operation is performed without the consent of such patient, the elements of technical assault and battery include malpractice and a violated duty on the part of the physician to his patient, and when an injury results to the patient, that such patient may waive the action for technical assault and battery and rely on his right to recover damages by reason of the wrongful and unskilful acts of the physician, which constitute a violated duty on his part. It would be unreasonable to say that because of the act on the part of the physician in performing an unnecessary operation without the consent of the patient, the elements of malpractice, wrongful acts, and a violated duty were not present and concurrent by reason of the acts of such physician; and while it may be true that such acts may constitute technical assault and battery, yet the injured patient may waive his right to proceed in an action for assault and battery and bring an action for the wrongful and unskilful acts of the physician, such acts constituting a violated duty on the part of the physician and the consequent injury to the patient, in which case the statute requiring an action for assault and battery to be brought within one year after its accruement is inapplicable.

Physician and Abortion When Fetus Has Lost Vitality

(Commonwealth v. Nason et al. (Mass.), 148 N. E. R. 110)

The Supreme Judicial Court of Massachusetts, in overruling the exceptions of the defendants who were convicted of using a rubber tube on the body of a woman with intent to procure a miscarriage, says that the defendants were husband and wife, and that the commonwealth introduced testimony tending to show that after the woman was brought to their house, the defendant wife, with the sanction and approval of her husband, inserted a rubber tube into the body of the woman and performed certain other operations on her, as a result of which a few days later the woman was delivered of a child about three months and two weeks advanced from conception.

A request that the jury should be instructed that an indictment for producing a miscarriage could not be maintained if the fetus had previous to the acts complained of lost its vitality, so that it could never have matured into a living child, was rightly refused. The offense created by the Massachusetts statute (General Laws, Chapter 272, Section 19) is complete when a defendant unlawfully uses an instrument on the body of a woman with intent to procure her miscarriage, and it is entirely immaterial that the fetus previous to the act complained of has lost its vitality, so that it never could have matured into a living child. Likewise, a requested instruction was rightly refused, which told the jury that if it found from the evidence that at the time the woman came to the defendants the fetus which she was carrying had already from the treatment administered by herself or one Duffy become dead and decayed, and that whatever the defendants did was merely to try to remove the remains of the dead fetus for the purpose of relieving the woman, the defendants could not be convicted. In regard to the contention of the defendants, suggested by the latter instruction, the judge instructed the jury:

"But they say, in addition, if these things were done there, if some of the things testified by the complainant and witnesses here or by the prosecutions were done, there is another view of them that takes them outside this statute, and there were no unlawful means employed to do what was done, and, therefore, no existing intent to commit any crime, and they respond to this action or indictment by the statement that one of the defendants is a physician, and what was done there was done on his judgment. Now then, a physician has a right to commit an abortion and, if it is done on the best judgment of that doctor and if his judgment corresponds with the average judgment of the doctors in the community in which he practices, it can cease to be illegal and becomes legal; just as legal as if he were delivering a woman with forceps five days before the period of gestation. If that defense is true, it is a complete defense if they both have acted under it. If he gave the advice and the woman defendant was acting under this advice, she is justified; but if he was giving advice that she did not know of and was taking on her own enterprise and undertaking to do something whereby she was not covered by a physician's advice, she cannot justify unless she was acting under his instructions."

This was sufficiently full and accurate to protect the rights of the defendants.

Contract to Withhold Information About Mistake

(Maryland Casualty Co. v. Fidelity & Casualty Co. (Calif.), 236 Pac. R. 210)

The District Court of Appeal of California, First District, Division 1, says that the plaintiff was, under a workmen's compensation policy, the insurance carrier of a company, one of whose employees in the course of his employment met with an accident through which he was ruptured, after which he was at the plaintiff's expense taken to a hospital for treatment. During the treatment an employee of the hospital, in the performance of his duties, delivered to a surgeon attending the injured man a preparation to be injected hypodermically. Through the negligence of the attendant, a different substance was substituted for that which should have been used, in consequence whereof the injection caused pain and suffering and aggravated the injury, delaying recovery and causing an additional expense of $1,000. The hospital carried an indemnity policy of insurance against liability for negligence of its employees, issued by the defendant. Both the plaintiff and the defendant knew of the mistake which had been made, and that in consequence thereof delay would result in the injured man's recovery. He knew nothing whatever concerning the matter. The defendant thereupon stated to the plaintiff that, if it would not inform the patient of the injurious effects of the injection of the wrong preparation, and if it would pay the sum by which the expenses of the treatment had been increased in the hospital, the defendant would reimburse the plaintiff for such additional outlay. The plaintiff agreed to this, and, after it had made payment to the injured employee of all moneys due from it as the insurance carrier of the employer, it paid the further sum of $1,000 in settlement of the additional expense arising as stated above. It was on this promise of reimbursement by the defendant that the complaint in the plaintiff's suit for $1,000 was predicated. A demurrer to the complaint was sustained on the ground that the contract was against public policy and good morals and therefore unenforceable; but the judgment rendered for the defendant is reversed by the district court of appeal, it seeming clear to it that there was nothing in the agreement here involved that in any manner condemned it, and that the plaintiff, having parted with its money in reliance thereon, was entitled to recover such amount.

The plaintiff had agreed at the request of the defendant to advance a sum for which the latter was solely responsible, on the understanding that the injured employee should be kept in ignorance of the arrangement. This understanding in no manner affected the patient's rights, and this court fails to see how vice was imported into the transaction by reason thereof, or how the arrangement was in any manner controlled or affected by public policy. The mere agreement of the parties not to disclose their arrangement to the injured employee in no manner encouraged a relaxed responsibility or a lessening of the care and watchfulness due to him, contrary to the interests of society, which would justify its denouncement. The plaintiff owed no duty to the employee to divulge to him the fact that his recovery had been delayed through carelessness. That was a matter between the patient and the institution employed to care for him, but which did not concern the plaintiff. No confidential relation of any kind was breached. Moreover, to render a promise of the character here involved illegal, it must have been for the sake of gain. Hearing denied by the Supreme Court of California.

May Testify After Making Examination for Attorney

(Leard v. State (Okla.), 235 Pac. R. 243)

The Criminal Court of Appeals of Oklahoma says that some four days after the offense charged in the information (the commission of rape) the county attorney had a physician make a physical examination of the prosecuting witness. The physician was not called as a witness by the state, but was offered as a witness for defendant Leard, and objection was made to the physician's testimony as being privileged. Section 589 of the Compiled Laws of Oklahoma of 1921 provides that:

> The following persons shall be incompetent to testify: . . . A physician or surgeon, concerning any communication made to him by his patient with reference to any physical or supposed physical disease, or any knowledge obtained by a personal examination of any such patient. . . .

The defendant, however, contended that the relation of physician and patient did not obtain in this case, for the reason that it was shown that the county attorney was present at the examination, and the physician was called by the county attorney. The court believes that the contention was well taken that the witness was competent and should have been permitted to testify. As expressed in the syllabus prepared by the court: A physician who makes an examination of a person at the direction of a prosecuting attorney, if he does not assume to act as a physician for such person, and is not called or employed as a physician by or for the person examined, is a competent witness to testify regarding the information gained in such examination.

Society Proceedings

COMING MEETINGS

American Pharmacological Society, Cleveland, Dec. 28-31. Dr. E. D. Brown, University of Minnesota, Minneapolis, Minn., Secretary.

American Physiological Society, Cleveland, Dec. 29-31. Dr. W. J. Meek, Science Hall, Madison, Wis.

American Society for Experimental Pathology, Cleveland, Dec. 28-30. Dr. E. B. Krumbhaar, Philadelphia General Hospital, Philadelphia, Sec'y.

American Society of Biological Chemistry, Cleveland, Dec. 28-30. Dr. D. W. Wilson, University of Pennsylvania School of Medicine, Philadelphia, Secretary.

Federation of American Societies for Experimental Biology, Cleveland, Dec. 29-31. Dr. Walter J. Meek, Science Hall, Madison, Wis., Sec'y.

Isthmian Canal Zone, Medical Association of, Ancon, Jan. 19. Dr. David L. Robeson, Ancon Hospital, Ancon, Secretary.

Sioux Valley Medical Association, Sioux City, Iowa, Jan. 19-20. Dr. R. F. Bellaire, Trimble Block, Sioux City, Secretary.

Society of American Bacteriologists, Madison, Wis., Dec. 29-31. Dr. James M. Sherman, Cornell University, Ithaca, N. Y., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal for a period of three days No foreign journals are available prior to 1920, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

30: 603-752 (Nov.) 1925

- *Etiology of Chronic Intestinal Indigestion. A. Brown, A. M. Courtney. G. A. Davis and I. F. MacLachlan, Toronto.—p. 603.
- *Tetany as Cause of Convulsions in Whooping Cough. G. F. Powers, New Haven, Conn.—p. 632.
- *Frequent Cause of Dyspepsia in Breast Fed Infants. K. U. Toverud, Oslo, Norway.—p. 642.
- *Inorganic Phosphorus in Blood of New-Born. Seasonal Variation and Relation to Rickets. E. A. Riesenfeld, I. Handelman and A. R. Rose, New York.—p. 646.
- *Intraperitoneal Transfusion of Citrated Blood. J. M. Sansby, St. Paul.—p. 659.
- *Urobilin Excretion in Children with Anemia. K. Merritt, New York.—p. 667.
- *Extreme Leukocytoses in Pertussis. R. P. Seitz, San Francisco.—p. 670.
- *Carbohydrate Metabolism of Normal Infant. F. F. Tisdall, T. G. H. Drake, and A. Brown, Toronto.—p. 675.
- *Craniotabes. C. U. Moore and H. G. Dennis, Portland, Ore.—p. 683.
- *Gummatous Osteoperiostitis of Skull in Congenital Syphilis; Two Cases. E. C. Dunham, New Haven, Conn.—p. 690.
- Literature on Infant Feeding for 1924. R. D. Moffett, New York.—p. 700.

Etiology of Chronic Intestinal Indigestion.—That a predominantly gram-positive aciduric intestinal flora of *B. bifidus* type is characteristic of chronic intestinal indigestion has been confirmed by Brown et al. That proteolytic activities are concerned in the production of the symptoms of chronic intestinal indigestion is indicated by the abnormally high ammonia content of the feces. A highly proteolytic spore bearing bacillus, isolated from the stools in two cases of chronic intestinal indigestion, has been found to be capable of extreme changes in the nature of its metabolic activities (in milk). "Bacillus A" forms, which constitute the predominant organisms of the typical flora in chronic intestinal indigestion are also variable in their metabolic behavior (in milk), though when cultured alone they are not usually strongly proteolytic. Some support is given by this work to the theory that a transformation of one to the other of *B. bifidus*, "Bacillus A" forms and a spore bearing bacillus, such as Noguchi brought about experimentally, may take place in the intestinal tract under some circumstances. Feeding experiments with white rats showed that they did not gain normally while being fed milk cultures of the beforementioned spore bearing bacillus but resumed the normal rate of gain as soon as the diet was changed. Cultures of the other organisms did not interfere with normal growth. Acidified milk and culturing with *Streptococcus lacticus* inhibited the growth depressing effect of one spore. *Streptococcus lacticus* (*Micrococcus ovalis*), the organism used in the preparation of the lactic acid and protein milk, which forms a part of the special high protein diets used in the treatment of chronic intestinal indigestion, established itself as the predominant organism of the feces soon after its infection has been begun. However, it probably takes a long time for it to oust completely the offending flora, which perhaps persists in a spore form. *Streptococcus lacticus* was very active metabolically in casein enriched low sugar milk and formed no harmful products.

Tetany Cause of Convulsions in Pertussis.—Powers calls attention to the fact that infantile tetany, and not anatomic injuries or an unknown toxin, is often the cause of the convulsions in whooping cough. Electrical hyperirritability of the nerves and a reduced calcium concentration of the blood serum may be the only means of recognizing the existence of tetany. A recognition of the rôle of tetany in this connection is important, that appropriate therapy for preventive as well as for curative purposes may be instituted.

Partial Inanition Cause of Dyspepsia in Breast Fed Infants.—In Toverud's experience, overfeeding with breast milk is a rare cause of dyspepsia. Partial inanition, however, is a frequent cause. The symptoms of inanition may vary widely. There may be merely weakness, constipation and weight loss, or there may be diarrhea, vomiting and irritability. The mechanism by which inanition causes the symptoms of dyspepsia is discussed.

Phosphorus in Blood of New-Born.—Reisenfeld et al. made 1,439 inorganic phosphorus determinations on the blood of mothers and their new-born infants. The inorganic phosphorus of the blood of the new-born infant was not affected by the previous habitat of the mother (that is, in the tropics or temperate zone). The time the mother spent out of doors during gestation showed no influence whatever on the inorganic phosphorus of the infants' blood. The diet of the mother was one of the controlling factors of the inorganic phosphorus content of the blood of the new-born infants. A definite seasonal variation of inorganic phosphorus was noted, which is in harmony with the recognized seasonal incidence of rickets. The curves of available sunlight hours and inorganic phosphorus of the new-born infant are parallel in the latter half of the year, the points of resemblance in the sunlight curve preceding that of the inorganic phosphorus curve by one month. The curve representing relative humidity, a hitherto uncorrelated factor, when compared with the inorganic phosphorus curve of the new-born infant, shows a striking parallelism throughout the year, the points of resemblance preceding the latter by two months. The close relation between relative humidity and the inorganic phosphorus content of the new-born infant's blood is explained as an accentuation of the effects of the ultraviolet rays by removing minute particles which act as a ray filter from the atmosphere.

Intraperitoneal Transfusion of Citrated Blood.—The effect of an intraperitoneally produced plethora of citrated blood on the hematopoietic activity of the bone marrow was studied by Sansby. It was found to have an inhibitory effect similar in nature to that produced when the citrated blood was introduced by the intravenous route. This substantiates further the viability of the red blood cells introduced by intraperitoneal transfusion.

Urobilin Excretion in Anemic Children.—From the series of cases studied by Merritt, in which the urobilin values are markedly lower than in the series of Bass, Denzer and Herman, it does not seem that the estimation of urobilin in children is as valuable a method as it is in adults, since there is often no marked increase when the clinical picture and blood findings would make the presence of blood destruction probable. There is little consistency either in the type of anemia or in the age of the child, as to the urobilin findings.

Leukocytosis in Pertussis.—Seitz reports two cases of pertussis with unusually high leukocyte counts. In one case the highest number was 192,000 per cubic centimeter; polymorphonuclears, 28 per cent.; lymphocytes, 61 per cent. In the other case, the peak was 162,500 leukocytes; 24 per cent. polymorphonuclears and 74 per cent. lymphocytes.

Carbohydrate Metabolism of Normal Infant.—From a review of the literature and their own results, Tisdall, Drake and Brown conclude that the average fasting blood sugar concentration in normal infants usually does not vary more than from 0.075 to 0.095 per cent. In the sixty-eight cases reported, the average value was 0.085 per cent.

Craniotabes Is Rachitic Manifestation.—Among 193 infants under 1 year of age, Moore and Dennis found cranial softening in 62 per cent. These cases indicated that craniotabes is rachitic.

Gummatous Osteoperiostitis of Skull.—In a series of 100 cases of congenital syphilis analyzed by Dunham, two children have presented themselves with gummatous osteoperiostitis of the skull, in addition to other lesions of congenital syphilis. The bones and skin were involved without evidence of involvement of the brain or meninges. The lesions healed rapidly under general antisyphilitic treatment.

American Journal of Anatomy, Philadelphia

36: 185-393 (Nov.) 1925

Origin of Germ Cells in Trionyx. C. S. Simkins, Memphis, Tenn.—p. 185.
Mitochondrial Elements of Spinal Ganglion Cells of Beriberi Fowls. Wen-Chao Ma, Peking, China.—p. 215.
Lineal Growth of Respiratory System During Fetal and Neonatal Life as Expressed by Graphic Analysis and Empirical Formulae. G. J. Noback, New York.—p. 235.

Order, Time and Rate of Ossification of Albino Rat (Mus Norvegicus Albinus) Skeleton. R. M. Strong, Chicago.—p. 313.
Musculature of Human Colon: Taeniae. P. E. Lineback, Atlanta, Ga. —p. 357.
Effect of Different Hydrogen-Ion Concentrations on Mitochondria in Liver Cell. J. T. Scott, Denver.—p. 385.

Hereditary Abnormalities of Viscera.—The inherited abnormalities of the viscera have been noted by Bagg in the descendants of a group of mice treated with comparatively light doses of unfiltered roentgen rays on five consecutive days. The visceral abnormalities are mainly defects of the kidney, which may vary from a partial, to a nearly complete atrophy of one kidney, to the congenital solitary kidney condition, and to complete absence of both kidneys. The right or left kidney may be affected with equal frequency, and there is apparently no sex difference in this respect. Animals with the congenital absence of both kidneys are born alive and are apparently of average weight and development in other respects. They live for about twenty-four hours. Blindness and various defects of the limbs, syndactylism, polydactylism, and especially club feet, are closely associated with abnormalities of the kidneys. One instance of situs inversus viscerum has been noted. Embryologic studies of young from strains with a high incidence of visceral abnormalities have shown that these defects are associated with blood extravasations, especially in the liver and testes, which are similar to those extravasations closely associated with the production of blindness and club feet. Selection has greatly increased the number of animals with visceral abnormalities in the experimental lines. The visceral defects are definitely inherited, are recessive to the normal, and when considered as one of the manifestations of a general tendency to abnormal structure, they approach the mendelian expectation in behavior.

Deaf Children.—Exactly one half of the children examined (290) by Shambaugh et al. were found to be congenitally deaf, while the other half had acquired ear trouble. Total deafness existed in 57.9 per cent. of the cases of congenital deafness and in 35.2 per cent. of the cases of acquired deafness. Partial deafness was found in 42.1 per cent. of the cases of congenital deafness and in 64.8 per cent. of the cases of acquired deafness. Vestibular responses were present in 75.1 per cent. of the cases of congenital deafness and in 62.07 per cent. of the cases of acquired deafness. Vestibular responses were absent in 24.9 per cent. of the cases of congenital deafness and in 37.93 per cent. of the cases of acquired deafness. A total absence of vestibular responses and total deafness were found in 17.5 per cent. of the cases of congenital deafness and in 26.2 per cent. of the cases of acquired deafness. Presence of vestibular responses and total deafness were found in 40 per cent. of the cases of congenital deafness and in 8.2 per cent. of the cases of acquired deafness. Absence of vestibular responses and partial deafness were found in 6.2 per cent. of the cases of congenital deafness and in 11.03 per cent. of the cases of acquired deafness. Presence of vestibular responses and partial deafness were found in 34.5 per cent. of the cases of congenital deafness and in 53.8 per cent. of the cases of acquired deafness.

Treatment of Infected Sigmoid Sinus.—Dixon has departed from the radical opening of the sinus, and even when the clinical findings are an infected thrombus with chills, sharp temperature fluctuations, leukocytosis, sweats, etc., he has limited the surgery to uncovering the vessel thoroughly until the normal sinus is reached, inserting a short gauze wick drain—not a pack—and leaving the wound wide open. Cases in which a thrombus has developed following an accidental tear of the sinus and late extremely septic cases are obvious exceptions. If the septic symptoms continue beyond forty-eight postoperative hours, then, without any anesthetic whatever, the exposed sinus can be thoroughly opened and drained. This two stage procedure, when necessary, also has the advantage of reducing the virulence of organisms within the mastoid process.

*Obstruction of Common Duct Among 1,000 Operations on Gallbladder and Bile Ducts. P. Truesdale, Fall River, Mass.—p. 968.

Relation of Measles to Diphtheria.—Lewis contends that measles frequencies are followed by increase of diphtheria cases. An increased morbidity from diphtheria occurs through the production of a tide of nasal carriers, and the isolation of these as well as of the avirulent nasal carriers during measles prevalence produces decreased morbidity of diphtheria. Diphtheria mortality would seem dependent in the main on measles epidemics for its excesses and variations. There would seem to be a factor bound up in measles operating later in time or even independently at occasional periods. Lewis is of the opinion that the same streptococcal complications as kill in measles, bronchopneumonia, etc., may likewise later take a similar toll from diphtheria. The important point to be established is that such streptococcal manifestations are not simulators as well as complicators. If they are never primary invaders and can gain their virulence only through their action as complicators, the theory of laboratory control by specific vaccination may control specific diseases.

Obstruction of Common Duct.—Seventy-five cases of common duct obstruction occurred among the 1,000 cases reviewed by Truesdale. The cause of obstruction in thirty-seven was stone; in twenty-eight it was pancreatitis, almost equally divided between the acute hemorrhagic and chronic types; in six it was cancer of the pancreas, and in four cases, the obstruction was due to traumatic cicatrization of the duct. Among the cases of stone in the common duct there were four deaths, representing an operative mortality of 11 per cent.

Treatment of Intestinal Obstruction.—The following suggestions are made by Orr and Haden for the treatment of acute intestinal obstruction: (1) In the very toxic patients at least 1 gm. of sodium chlorid per kilogram of body weight (1 gm. for each 2.2 pounds) should be given as an initial dose. This is best given in 2 or 3 per cent. solution subcutaneously and 5 per cent. intravenously. With both methods the solutions should be given slowly. (2) In the severely toxic and dehydrated cases, treatment with salt solution should always be given before operation and continued immediately after operation. At least five liters of water should be given with the salt in the first twenty-four hours. (3) As a general guide to the treatment of intestinal obstruction, the *five factors to be remembered are, the mechanical obstruction,* dehydration, starvation, toxemia and drainage of the obstructed bowel.

Roentgen-Ray Irradiation over Spleen in Anaphylactic Diseases.—Waldbott believes that his results in ten cases are sufficiently conclusive evidence to warrant further investigation into the value of roentgen-ray irradiation over the spleen in anaphylactic diseases. It is believed that with this method a cure can be facilitated by stimulation of the function of the spleen which is greatly involved in the production of antibody. In order to interpret any results from this treatment, it is essential that the diagnosis of anaphylactic asthma must be definitely established, since other types of "asthma," i. e., thymus enlargement or chronic bronchitis, cannot be expected to be benefited.

Tumors of Testis. F. C. Schuldt, St. Paul.—p. 686.

Acute Arteriomesenteric Ileus.—McLaughlin is of the opinion that acute arteriomesenteric ileus may be a more frequent cause of postoperative vomiting than is generally supposed. He reports two cases—an appendectomy and a cholecystectomy—in which this complication occurred. The treatment consists in elevating the foot of the bed and gastric lavage.

Skin Diphtheria.—Friedel is convinced that skin diphtheria would be found more often if cultures were taken from slow healing wounds. He reports two cases in each of which a finger was the seat of the infection. In one of the cases the knee and dorsum of the foot were also affected. In this case, treatment consisted in removing the necrotic tissue with a sterile applicator and applying 10 per cent. silver nitrate once a day.

Frequency of Insulin Dosage and Increased Threshold. H. E. Marchbanks Pittsburg, Kan.—p. 434.

Traumatic Fracture of Vertebral Column.—Experience has convinced Moore that traumatic fractures of the vertebral column unaccompanied by cord or nerve symptoms are very frequently unrecognized until accidentally discovered in the course of a roentgen-ray examination made on account of pain and stiffness of the back, or pain referred to some other part of the body. Limitation of motion or stress bearing capacity of any vertebra affects the entire column. Spinal rigidity or weakness is a major disability increasing in importance as descent in the social scale occurs. Accurate, early roentgen-ray diagnosis of questionable cases is essential, since the results are so disastrous if correct treatment is omitted.

Tooth Destruction in Pregnancy.—Kerwin urges that all necessary dentistry during pregnancy should be done regardless of the duration of pregnancy. The aim at tooth preservation is one of the obstetrician's duties. Better teeth can be given to the new-born by proper prenatal care. Pregnant women should use frequently an alkaline mouth wash and take calcium throughout the pregnancy.

*Hemophilia; Two Cases. M. G. Wohl, Omaha.—p. 442.

Cylindroma of External Auditory Canal.—Tyler reports a case of cylindroma of the external auditory canal which contained microscopic evidence of parotid tissue. The microscopic findings support the theory that the mucoid material found in cylindromas is really a secretion of the cells making up the parenchyma of the tumor rather than the result of hyaline degeneration as advocated by some. The presence of parotid cells in the tumor bears out the theory that this particular tumor arose at the site of a parotid cell nest in the wall of the external auditory canal.

Administration of Liver Extract in Hemophilia.—A fresh extract from the rabbit's liver, which is rich in thrombokinase, was used by Wohl in checking hemorrhage in two cases, after all conventional methods had failed.

*Surgical Treatment of Cancer; Results. G. W. Crile, Cleveland.—p. 1019.
*Present Status of Treatment of Cancer. B. T. Simpson, Buffalo.—p 1022
Roentgen Ray in Cancer Therapy. B. F. Schreiner and B. T. Simpson, Buffalo—p 1025

Results of Cancer Treatment.—Of 3,414 cases of cancer reviewed by Crile, in which treatment was by all methods, only 926 patients have been heard from, and of these 208 have survived a period of five years or over. One hundred and forty-five of these were breast cancers; fifteen were thyroid cancers and eleven each were cancers of the stomach and of the large intestine, including the rectum. Fifteen were uterine cancers—eight of the cervix and seven of the fundus.

Status of Treatment of Cancer.—Simpson says that it is evident that the unfavorable results obtained in the treatment of cancer of the breast are due to premature metastases. These, most probably, are brought about by excessive handling of the tumor by the patient, and very often by a too vigorous examination by the physician. Simpson urges that there should be instituted a widespread educational attack on this aspect of breast cancer. The danger of manipulation should be brought home, not only to the laity, but also to the medical profession. It should be impressed on the latter that it is not always necessary to make a definite clinical diagnosis of cancer. The presence of a tumor in the breast, whether it is malignant or not, is sufficient evidence to justify an immediate operation.

Oklahoma State Medical Association Journal, Muskogee

18: 253-278 (Nov.) 1925

Orthostatic Albuminuria. T. H. McCarley, McAlester.—p. 253.
*Perinephritic Abscess. J. Z. Mraz, Oklahoma City.—p. 256.
*Acute Nephritis Following Peritonsillar Abscess. J. G. Smith, Bartlesville—p 261

Arterial Accidents in Brain. A. D. Young, Oklahoma City.—p. 264.
Possibilities of Cooperation. A. C. McFarling, Shawnee.—p. 265.

Perinephritic Abscess.—Eleven cases of this type are reported by Mraz. Three were leftsided and eight rightsided; six can be classed as metastatic; four, as of renal origin and one, an extension from an inflamed retrocecal appendix. Four of the six metastatic cases gave a definite history of peripheral infections just prior to or at the time of beginning of symptoms. Two of the eleven patients sustained an injury at the time of beginning of the trouble. One of the injuries was of metastatic and the other of renal origin. Needling was performed in six cases; in two the pus was not located. In one of these the pus was later found anterior to the lower pole and in the other at the upper pole of the kidney. Incision and drainage were done in each case. There were no deaths.

Acute Nephritis Following Peritonsillar Abscess.—Smith reports three cases in which an acute glomerular nephritis manifested itself about two weeks after the patients had recovered from a peritonsillar abscess.

Philippine Journal of Science, Manila

28: 173-310 (Oct.) 1925

*Dysentery Carriers in Philippine Islands. A. Vazquez-Colet.—p. 173.

Dysentery Carriers in Philippines.—The existence of healthy carriers of *B. dysenteriae* in the Philippine Islands has been demonstrated by Vazquez-Colet. The proof was carried out by isolation of cultures which, according to standard methods of identification, proved to be *B. dysenteriae*. In 3,328 examinations fourteen carriers were found, of whom seven harbored the Shiga type, six the Flexner type, and one both Flexner and Shiga types. Agglutination tests were performed with the carriers' serums and with the corresponding culture isolated from the carriers, as well as with stock cultures of the Shiga and the Flexner types. Usually the serum of the carrier agglutinated its own strain to a lesser degree than the stock cultures, and at times a considerable inhibition zone was noticed with the carrier's serum and its own strain. All of the cultures belonging to the Shiga type isolated from the carriers were pathogenic for white mice, and some of them were strongly toxic to rabbits. The cultures belonging to the Flexner type, isolated from carriers, were found to be of low virulence.

Treatment of Insomnia.—Dyspepsia, constipation and flatulence, either in the stomach or colon, in Hutchison's opinion, are common but usually overlooked causes of insomnia. It may, therefore, be worth while, when no physical cause for the insomnia is evident to try the effect of an alkaline carminative draught at bedtime. Mental discomfort, which will usually take the form of some anxiety state, is another factor in the etiology of this condition. Hutchison believes it to be cant to say that hypnotics should only be used in insomnia as a last resort. He suggests that the fear of establishing a "habit" is a bugbear, and that the possibility of the insomnia becoming a habit is a much more real danger. There are few cases of bad insomnia in which the prescription of an hypnotic is not required at some stage or other. There is a large choice of drugs for this purpose, ranging in potency from the bromids to phenobarbital. The bromids are only indicated in the mildest cases, but the urea bromin compounds are better. Of the more potent drugs the barbital group is, on the whole, the best and barbital sodium, in 7½ grain (0.5 gm.) doses, will meet most indications. Paraldehyd has the disadvantage of advertising itself too openly, but chloral has probably fallen too much into disuse. It has the drawback of irritating the stomach, but that can be overcome by suitable methods of administration, and although it is perhaps wise to avoid it in cases of myocardial degeneration it is otherwise quite safe. Chloralamid is too uncertain in its time of action to be relied on. Of the other hypnotics, trional, from its somewhat delayed action, is specially indicated in those cases in which the patient is awake only in the latter part of the night (so-called internocturnal insomnia). Sulphonal though largely used in asylums is inferior to trional. Phenobarbital is unnecessarily powerful for use except in exceptional circumstances, and morphin should never be administered in primary insomnia outside a mental hospital.

Prophylaxis of Mental Disorder.—In order to disarm popular prejudice, Rolleston would label the psychiatric clinic "Nervous and Psychiatric Department." It should be part of a general hospital, closely connected with a university, so as to provide facilities for research and for teaching medical students, and it would appear that in addition students interested in the experimental and other aspects of psychology would benefit from the opportunities thus provided. While a central laboratory in connection with a psychiatric department attached to a general hospital and a university is the ideal arrangement, psychiatric or mental clinics situated at a distance from university centers should have clinical laboratories for routine work. The prevailing note in the care of early and recoverable patients should be sympathetic conciliation rather than the forbidding coercion—cheerfulness and helpfulness instead of severity and repression.

Rheumatic Infection in Childhood.—The onsets of acute rheumatism in the child, according to Poynton are: (1) cases showing fulmination, the patients readily recognized as being gravely ill; (2) a large group of cases in which sore throat, arthritis, and morbus cordis are the first symptoms; (3) another large group in which chorea and morbus cordis are the beginning symptoms; (4) a group in which chorea only starts the disease; (5) a group in which heart disease alone may take the form of dilatation following sore throat as the cause, and (6) a group in which the rheumatism begins insidiously, usually with multiple symptoms that remit and exacerbate, thus producing the "rheumatic state." Poynton believes the tonsils to be an important site of infection. Skilled enucleation will not prevent a first attack of rheumatism and acute carditis of extreme severity occurring some years later. However, an acute and crippling attack of carditis may directly follow removal of the tonsils in the patient with rheumatism. The successful removal of unhealthy tonsils is a valuable prophylactic step if, undeterred by exceptions, we view the problem on broad lines. Poynton believes that every case must be considered as an entity. He does not favor routine action. He holds that the teeth and gums of children should be kept as healthy as possible, but he can trace no clear connection between acute rheumatism and dental disease in childhood.

Ovarian Extract in Puerperal Insanity.—Five cases are recorded by Wilson and Christie to illustrate the value of the hypodermic injection of ovarian extract in puerperal insanity and possibly in other forms of acute confusional insanity. It probably acts by bringing about the reestablishment of menstruation, because if the patient can be got to menstruate her difficulties are over. The mental breakdown is due to a temporary deficiency in ovarian secretion, a deficiency that can be made up.

Bacteriology of Subacute Infective Endocarditis.—The esults of Wright's study may be summed up in the following way: When the blood culture has been positive the bacteria re readily demonstrated in the valve lesion. When there has been a terminal invasion by a pyogenic organism there re usually features in the lesions which suggest that this has occurred. In the nonbacteremic cases bacteria are present in he vegetations in the characteristic position but they seem to differ somewhat in appearance from those seen in bacteremic cases, the differences being such as to suggest that they are undergoing disintegration. While these changes are to be observed to some extent in all cases, they are particularly characteristic of the nonbacteremic cases. In one of these, as evidenced by six negative blood cultures, the condition had asted for seventeen months. It must be supposed, then, that he organisms may remain *in situ* for a very long period without appearing in the blood stream. This may be due to the fact that the organisms are dead or that they are prevented from reaching the blood stream by the physical barrier of the thrombus material separating them from it. At the same time they are protected from the phagocytic cells by the same barrier. Consequently, a process of removal by solution or autolysis is necessary and is apparently a very tardy one. Whether the process ever does go on to complete removal and subsequent healing by fibrosis still remains doubtful, but it would appear to be quite possible, though apparently rare. It is clear that disappearance of the septicemia is by no means a cure of the disease which is always fatal in both septicemic and nonsepticemic cases. It is possible that in some of these cases there has never been a septicemia. In others it may have disappeared after a time and the bacteria may have remained in the valve lesion. Cure of the disease would mean the complete obliteration of the focus. Finally, it appears likely, although further evidence is necessary, that the organism responsible for the nonbacteremic cases is of the same nature as that in the septicemic cases, a streptococcus.

Complement Fixation with Bilharzia.—Fairley asserts that the antigen which reacts with specific antibody in the complement fixation reaction for bilharzia is a lipoid or lipoidal complex of colloidal nature. Many of the experimental observations enumerated in this paper are in complete disagreement with the published data of Le Bas, who would identify the antigenic factor in bilharzia antigen with the protein or allied constituents of these extracts.

Normal Weight of Thymus.—The records of 337 healthy persons under 16 years of age, who died either from an acute medical or surgical condition within twelve hours of its onset, or immediately after or within a day of some accident to which death was directly attributable, were reviewed by Bratton with reference to the weight of the thymus. It was found that the absolute weight of the thymus increases rapidly during the first two years of life, then changes little (with a tendency to decrease) till the seventh year, when it again increases, to fall slightly after the eleventh year. The weight of the thymus increases relatively to the body for part of the first six months and then decreases rapidly; after the fifth year the relative decrease continues at a slower rate and is apparently interrupted by a transitory increase during the eighth year. The thymus in the male is heavier at birth and for the first four years of life, after which the weight is approximately equal in the two sexes till the eleventh year, except that a rise and fall about the eighth year occurs in the female; after the eleventh year the thymus tends to be absolutely heavier in the female. There is little difference in the weight of the gland relative to the body in the two sexes; in general it is greater in the male during the first five years of life and afterward in the female. The absolute and relative weights are slightly greater in Jewish than in British children, but the differences are too small to be considered significant.

Experimental Tar Necrosis and Cirrhosis of Liver.—The investigation described by Davidson was undertaken because, in experiments in which coal tar had been applied to the skin of rabbits' ears to produce cancer, it was found that in several of the animals cirrhosis of the liver had supervened. The acute changes are similar to those found in acute yellow atrophy in man. The chronic changes, including regeneration of the liver, closely resemble those of typical atrophic cirrhosis. These observations suggest that the changes observed in acute yellow atrophy and atrophic cirrhosis of the liver are different stages in one process. The regenerated tissue is still susceptible to the irritant. The arrangement of the cells in the regenerated tissue is irregular and in some instances adenomatous growth occurs.

Rôle of Mitochondria in Cell Injuries.—The main conclusion that follows from the observations made by Smith and Rettie is that cell degeneration (cloudy swelling and fatty degeneration) involves a destruction of the mitochondria. These results confirm Cowdry's general conclusion that in changes in mitochondria are to be found the earliest indications of cell injury. The recovery of a cell from degeneration involved a rebuilding of mitochondria and restoration may take place if the damage has not been too severe. It still remains to determine not only the limits of destruction from which recovery may take place but also the conditions that are favorable or essential to the process.

Value of Diaplyte Tubercle Vaccine.—Experiments were made by Douglas et al. to determine whether in tuberculous guinea-pigs diaplyte tubercle vaccine might show any beneficial effect when used over long periods, its administration being begun before, simultaneously with or after the infection of the animals with tubercle bacilli. The results obtained in these experiments correspond very closely with those already recorded by Kettle, Schutze and Bronfenbrenner and Straub. The conclusion which may be drawn is that weekly doses of 0.5 c.c. of diaplyte tubercle vaccine, derived from a strain of tubercle bacilli other than that employed by Dreyer, whether used as an immunizing agent previous to the production of a tuberculous infection, or given as a curative agent from the date of the production of the tuberculous infection, or given after the tuberculous lesions have become well established, is of no avail for combating, in guinea-pigs, tuberculosis resulting from infection with living bacilli of the same strain as that which was used for the preparation of the diaplyte vaccine.

Effect of Splenectomy on Erythrocytes.—Mole removed the spleen or half of it in seventeen rabbits and studied the effect of this on the number of erythrocytes, the number of reticulated erythrocytes, the resistance of the erythrocyte to hypotonic saline and saponin solutions and the number of white cells. Usually a decrease in the number of erythrocytes occurred almost at once; in about a week they began to increase and in two months they were usually more numerous than before the operation. The decrease was usually less marked and the increase began earlier and was more marked after partial splenectomy. The erythrocyte decrease was associated with a considerable reticulocyte increase during the first two weeks, suggesting that the increase in erythrocytes at this period was due to a persistence of the old cells which would have been destroyed but for absence of the spleen. The increase in the erythrocytes two or three months after splenectomy was associated in rather more than half the rabbits with a slight increase in their resistance to hypotonic saline solution. Their resistance to saponin solution was apparently unchanged. Removal of the whole or half the spleen in adult rabbits produced an increase in the number of white cells, chiefly leukocytes, in the first week. This increase was evidently of inflammatory origin, being more marked and persistent after partial splenectomy.

Action of Thujone.—Florey's observations would seem to justify the conclusion that thujone acts directly (in contradistinction to an immediate action on the cerebral blood supply producing fits) on the motor cells of the cerebrospinal axis, as fits are produced in the intact, the decerebrate and the spinal animal. The vasomotor and the respiratory centers are also vigorously stimulated. The evidence is against the participation of the vagus center in the stimulation.

Milk Freed from Chlorids in Treatment of Edema.—Carrayrou obtained excellent results using milk freed from chlorids in persons with enormous edema and ascites, from a failing heart. The condition of the patients had remained precarious in spite of different heart tonics and an exclusive milk diet. As soon as the ordinary milk was replaced by milk freed from sodium chlorid and potassium chlorid, the output of urine increased, and the edema disappeared in a few days. The daily output of urine, which had not surpassed 300 gm. in one patient, reached 1,250 gm. after six days of this treatment. The edema reappeared when ordinary milk was used again. Recurring attacks of pulmonary edema were arrested in another case when the modified milk was taken. The same benefit was manifest in nephritis and uremia. Puglia's method of dialyzing the milk allows the passage of all salts and phosphates except sodium chlorid and potassium chlorid. A small quantity of lactose is added in order to replace that retained by the dialyzer, and then the milk is sterilized. This chlorid free milk may prove an effectual adjuvant to tonics in heart and kidney disease.

Pathogenesis of Myasthenia.—Marinesco reports two cases of myasthenia which may be ascribed to disturbances of the vegetative nervous system, of suprarenal origin. Reduced formation of substances controlling the vascular tonus appears to be responsible for the inverted vasomotor reaction, consisting in dilatation of the vessels during voluntary muscular contractions. This probably affects the acid-base balance of the muscle fibers, stimulating the activity of the hydrolytic and lipolytic ferments, and thus creating lesions of the muscles. The inverted vasomotor reaction was absent in one patient, who improved remarkably under epinephrin treatment, while it existed in the other with still pronounced myasthenia. Changes in the suprarenals may also entail exaggerated functioning of the parathyroids, with consequent hypercalcemia. Subcutaneous and intramuscular injections of epinephrin appeared to be as effectual as the intravenous.

Radial Paralysis of Rheumatic Origin.—Dufour and Blondel describe a case in a man, aged 32. Sudden paralysis of the radial nerve had preceded the acute rheumatism manifestations in the shoulder and wrist. The peculiar feature was the restriction of the paralysis to a single nerve; neuritis complicating rheumatism is usually multiple. The paralysis may have been caused by the virus of the acute articular rheumatism. Salicylate treatment proved effectual.

Cirrhosis of the Liver with Bronzing in a Syphilitic.—Lévy and Jausion report that the skin returned to its normal color under treatment for the syphilis, and the symptoms of mild diabetes subsided with the melanoderma.

Basal Metabolism in Course of Experimental Cancer.—Remond, Sendrail and Lassalle found the basal metabolism reduced in eight rabbits with tar cancer. They are inclined to ascribe the fact to an insufficient functioning of the thyroid gland, caused by the tar, thus favoring the appearance and development of the tumor. Their further research proved that while hypercholesteremia is usual in the precancerous stage, there is a decrease of the free cholesterol and lecithins with a developed tumor. The proportion of fatty acids is increased. The authors point to the recent work of Carrel, Mertens and Lipschütz tending to confirm that tar cancer is rather a tissue manifestation of a general derangement than a product of irritation.

Oxygen Content of Methemoglobin.—Balthazard and Philippe acknowledge their error in agreeing formerly with Jäderholm. After they had repeated Jäderholm's experiment in a vacuum from which oxygen had been completely expelled, it showed that methemoglobin is transformed directly into hemoglobin, without its passing through the stage of oxyhemoglobin. The latter appears to contain twice as much oxygen as methemoglobin.

Action of Ultraviolet Rays on Lymphoid Tissue.—Jolly concludes that the action of ultraviolet rays on lymphoid organs is essentially similar to that of the roentgen and radium rays. The lesions are confined to the exposed area, not affecting the tissues deeper than 0.5 mm. at most. The latency time is about the same as with roentgen rays and certain toxic substances.

Tuberculous Mesenteric Glands in Young Child.—Acuña and his co-workers observed the case in a child, about 2 years old, whose sister had died from tuberculosis, and who had been in contact with a tuberculosis suspect. It died soon after an exploratory operation showing a mesenteric tumor. Cheesy degeneration of the mesenteric glands, and miliary tuberculosis of lungs and viscera were found on microscopic examination. Infection probably appeared during the first year, and was of intestinal origin. [A more detailed report, with photomicrograms, was published in the *Semana Médica*, **2:**617 (Sept. 10) 1925.]

Acetylene in General Anesthesia.—Heymans and Bouckaert used acetylene for anesthesia in about fifty operations, lasting from a few minutes to three hours. The usual initial phase of excitation did not occur; the patient inhaling the anesthetic deeply went under without resistance or agitation. A combination of 80 per cent. of acetylene with 20 per cent. oxygen, induced insensibility and muscle relaxation in three minutes. The toxic effect of acetylene seemed to be very slight, since the subject wakened rapidly and in a better general condition than after chloroform or ether. The disadvantages of the method, namely the large size of the apparatus, the complicated technic and the inflammability of acetylene are offset by its advantages.

Influence of Acidosis and Alkalosis on Chronaxia.—De Waele injected acids and alkalis into the lymph spaces of frogs and turtles. Chronaxia and rheobasis appeared to be decreased in acidosis, and increased in alkalosis.

Cholesterol Content of Blood in Shock.—Zunz and La Barre's experiments on guinea-pigs repeatedly showed a marked increase of cholesterol in the plasma and total blood, and a slight reduction of fatty acids in the plasma during an anaphylactic shock.

Action of Lytic Agent on Culture Antigen.—McKinley's research confirmed Bordet's theory that the lytic agents are bacterial products, important in the development of cultures. They may modify the specific antigen of the micro-organisms.

Active and Passive Transmissible Lysis.—Bordet experimented with a colon bacillus displaying a lytic action on the Shiga bacillus. No lysis occurred as long as the colon bacillus (A) was exposed to its own lytic element. This represented the normal physiologic condition. Lysis appeared when the colon bacillus (A) was submitted to a lytic element from a certain other variety of the colon bacillus (B). The colon bacillus (A) adapted itself to the new lytic element and continued to reproduce it even after it had been isolated from its influence. This is the spontaneous or active lysis. Exposed to a lytic element from a different species, the colon bacillus reproduced it only as long as the contact persisted, but not otherwise. This is the passive or induced lysis. Bordet assumes that these facts confirm his theory of a transmissible autolysis.

Paris Médical

57: 397-412 (Nov. 14) 1925

Prolonged Acute Bronchitis. G. Rosenthal.—p. 397.
*Sedimentation and Pneumothorax. Papanicolau and Weiller.—p. 400.
*Reaction of Liver to Arsphenamin. L. Masson.—p. 403.
*Tubercle Bacilli in Urine. G. Esquier.—p. 405.
*Ocular Spasms After Epidemic Encephalitis. D. Paulian.—p. 409.

Sedimentation Test as Guide in Artificial Pneumothorax.—Papanicolau and Weiller's observations were made on patients with artificial pneumothorax induced for grave pulmonary tuberculosis. Sedimentation was usually rapid in these cases, but it changed immediately after the operation, becoming notably reduced if the compression involved the most pathologic part of the lung. With imperfect compression, and consequent aggravation of the condition, the speed of sedimentation became rapid again. Appearance of a pleural effusion was accompanied by acceleration of sedimentation. The speed increased still more with a purulent exudate, while it was normal in case of resorption of the pleural fluid. Thus the sedimentation test may demonstrate the effect of an artificial pneumothorax or thoracoplasty, or even reveal menacing complications.

Action of Arsphenamin Injections on the Liver.—Masson states that he has never encountered an instance of toxic jaundice from intramuscular injections of sulpharsphenamin, in his large experience. He reports a case in which these injections apparently cured syphilitic jaundice. Experiments on rabbits indicated that intramuscular injections of arsphenamin are less toxic for the liver than the intravenous. Their action is the same, although somewhat retarded.

Detection of Tubercle Bacillus in Urine.—Esquier used a simplified Gauthier method for examination of the urine in 111 patients. The tubercle bacillus could be detected in over 33 per cent. of the cases of tuberculous epididymitis; in 88 per cent. of tuberculosis of the bladder, and 78 per cent. of renal tuberculosis. He thus showed up the bacilli in five minutes in 95 per cent. of the cases.

Paradoxic Ocular Spasms After Epidemic Encephalitis.—Several of Paulian's patients presented, among other sequelae of epidemic encephalitis and parkinsonism, spasms of the orbicularis muscles. Besides spasmodic retraction and relaxation of the orbicularis palpebrarum and oris, there was speech disturbance of the stuttering type and paradoxic dyskinesia.

Iodin in Pulmonary Tuberculosis. Nigoul-Foussal.—p. 1478.
*Treatment of Spastic Ileus. T. Asteriadès.—p. 1480.

Deficiency Diseases.—Mouriquand considers deficiency disturbances from inadequate alimentation, defective digestion or absorption, and from defective nutrition. The latter includes deficient transformation, distribution and assimilation of the elements of the food. Instances of alimentary deficiency are vitamin C deficiency which is manifested by scurvy; vitamin A deficiency, inducing hemeralopia, and vitamin B deficiency, producing the beriberi syndrome. The deficiency of digestive origin is due to insufficient mastication or deglutition, or to obstacles in the gastro-intestinal tract. An insufficient secretion of digestive juices may impede the absorption of the food. Deficient nutrition or deficient metabolism of the cells is provoked by lesions of the liver, suprarenals, and particularly of the bone marrow, the organs controlling the metabolism. In these cases the food may be appropriate, and digestion normal, but assimilation of the alimentary substances will be defective.

Sugar in Treatment of Epilepsy.—Wladyczko induced convulsions in rabbits, mice and dogs by injections of insulin, with the consecutive hypoglycemia. He also noted an increase of epilepsy cases in Russia at a time when the supply of sugar was scarce. Thereupon he tried the sugar treatment in epileptics with hypoglycemia. In eighteen cases the seizures became rarer and milder; in five they appeared only once in from four to six months, while before the treatment they occurred every day in one patient, and three or four times in a month, in the others. Since blood with a reduced sugar content may irritate the nervous centers, causing convulsions, it seems that administration of sugar should prevent them. The effect of sugar may be ascribed also to an enhancing action on drugs, given at the same time. From 50 to 100 gm. of glucose, dissolved in water, with lemon juice, or 200 gm. of sugar was given daily by the mouth. The amount of sugar was reduced to 5-25 gm., when sweet fruits or syrups were being taken.

Immunization Against Scarlet Fever.—Bourcart immunized Dick positive subjects by repeating the Dick test on new areas of skin at two or three days' intervals, and keeping this up until the reaction veered to negative. In his thirteen cases, this occurred after three to nine applications of the Dick test in eleven.

Intraspinal Anesthesia for Spastic Intestinal Occlusion.—Asteriadès says he applied intraspinal anesthesia in three cases of spastic ileus, following abdominal operations, and the complication subsided promptly. Thus the patient was saved by the intraspinal anesthesia possibly from a futile laparotomy. The spastic occlusion appears suddenly, during the first few days after an operation, while a mechanical occlusion from adhesions or volvulus does not develop until ten to thirty days after the laparotomy. The differentiation from acute peritonitis may be based on the normal pulse and temperature in spastic occlusion. Vigorous peristaltic contractions of the nonaffected portion of the intestine above the region of the spasm may be visible sometimes. This is a valuable diagnostic sign when encountered. He used procain for the intraspinal anesthesia; the spasm was arrested at once, and stool was voided explosively in less than two minutes.

*Social Hygiene and Mortality. A. Gigon and F. Kinzler.—p. 1033.

Cystic Mamma.—Askanazy deals with the latent stages of cystic epitheliofibrosis of the breast (Reclus' disease). He found them in 33 per cent. of elderly women and in 25 per cent. of girls and women under 40 years of age. The epithelium of the breast is easily irritated, and proliferates in a degree that would arouse suspicions in other organs. Extirpation of the tumor is indicated in the stage of a tubulopapillary cystoma. Extensive intervention is necessary if the spaces are overcrowded with heaps of epithelial cells, containing mitoses, and if lymphocytic infiltration is beginning. There is no question about the malignancy if the epithelium invades the lymphatic spaces of the stroma.

Social Hygiene and Mortality.—Gigon and Kinzler find that the increase in life expectancy in men is smaller in Switzerland than in Germany. It is the opposite with women.

Liver and Postencephalitic Condition.—Graziani found in eleven patients with postencephalitic syndromes only very slight, if any, clinical signs of a disturbance of the liver. The anatomic changes at necropsy in three other cases were also only slight.

Riforma Medica, Naples

41: 985-1008 (Oct. 19) 1925

Hygroma of Bursa Subserrata. L. Torraca.—p. 985.
*Coma from Interruption of Insulin Treatment. F. Schiassi.—p. 990.
*Experimental Cancer Vaccination. G. Tizzoni et al.—p. 995.

Coma from Interruption of Insulin Treatment.—Schiassi found a large increase in blood sugar in a diabetic patient as soon as the action of insulin ceased. Administration of a new small dose of insulin reduced the glycemia—probably refilling the glycogen deposits in the liver, which are particularly changeable in diabetes. Simultaneous intravenous *injections of glucose in coma not only prevent the danger* from hypoglycemia, but also serve to replenish the liver glycogen.

Experimental Cancer Vaccination.—Tizzoni, Centanni and De Angelis exposed an emulsion of cells of Ehrlich's mouse adenocarcinoma to the action of radium. The cells lost their *pathogenicity after twenty-four hours, but this emulsion* injected near the tumor of other mice, induced its complete resorption. It was ineffective if irradiated for forty hours.

*Therapeutic Action of Sugar in Certain Dermatoses. P. Conca.—p. 498.
The Practical Value of the Wassermann Test. U. Cavallucci.—p. 500.

Early Sign of Peritonitis.—Sorrentino states that the Sgambati urine test was positive in twenty-four of twenty-five cases of acute peritonitis, sometimes before the clinical manifestations had developed, while he never obtained a positive response in simple contusions and other noninflammatory abdominal affections.

Sugar Treatment in Dermatoses.—Conca reports that intramuscular injection of 2 or 5 c.c. of an 8 per cent. solution of saccharose favorably modified the course of eczema, psoriasis and prurigo in a number of his cases. The smaller doses seemed to act by influencing the endocrine system, the larger by a vasoconstrictor effect. In one young man with an intensely itching eczema on the legs and scrotum of six months' standing, the pruritus gradually subsided completely in two weeks and no further treatment of any kind was required after the fifteenth day.

Malta Fever.—Domingo remarks that four of his laboratory assistants contracted the disease in their four years of research on melitensis infection, with analysis of 180 cases and extensive animal experiments. Excellent results in treatment were realized with an emulsion of ox-gall-treated melitensis micrococci by the mouth. In rebellious cases, protein therapy proved a useful adjuvant, as likewise epinephrin in cases of hypotension. Of sixty-three patients, 65 per cent. were cured in less than two weeks; 17.3 per cent. required thirty days, and 6.2 per cent. up to forty-five days. There was recurrence only in 11.5 per cent.

Metabolism After Milk Injections.—Butomo observed *an increased elimination of nitrogen and phosphates after parenteral injections of milk in normal dogs and in those infected* animals which had had no increased elimination of these substances before the injection. Where the infection had raised the azoturia and phosphaturia, milk injections reduced them. Patients who reacted to protein treatment, with a lowering of the elimination of nitrogen and phosphates, had a favorable prognosis. It was the opposite when the elimination was enhanced.

Metabolism in Pregnancy.—Klaften and Stecher found a low specific dynamic action in too young and in too old primigravidae, also in dropsy and in the kidney disease of pregnancy.

Diagnosis of Univitelline Origin.—Siemens shows how unreliable the history of twin delivery is. Even the cases in which records were kept were not examined sufficiently: The chorion is more important than the placenta. Separate membranes do not disprove the possibility of a univitelline origin: Only a third of these pairs are of different sex (against the expected 50 per cent. if all were bivitelline). The percentage of different sex in all twin pregnancies shows that 25-33 per cent. should be univitelline. This alone speaks for the probability of occurrence of univitelline twins with separate membranes. A careful examination of the twins points also toward this possibility.

Ovaries and Blood Calcium.—Heyn and Haase found high serum calcium figures in grave functional amenorrhea, and low values in the first year after castration. They conclude that these findings cannot be explained by a direct influence from the ovary on the blood calcium.

Germ Content of Vaccines.—Dold finds that a control of commercial vaccines by counting of the germs is impossible and useless. The methods of counting involve grave errors. An estimation of the turbidity is sufficient. The number of germs decreases because of the autolysis, although the antigenic value does not necessarily deteriorate by it.

Sympathetic Paraganglion on Left Heart.—Wassermann draws attention to the chromaffine tissue discovered by Wiesel in the neighborhood of the left coronary artery. Similar to Dünner's explanation of the carotid glomus as a receiving organ for the "vagus pressure experiment," he believes that Wiesel's organ may be the origin of the reflex angina pectoris.

Treatment of Simple Abortion.—Fink denounces the use of sounds, abortion forceps and sharp curet in treatment of abortion. Drugs (quinin, pituitary, ergot) are valuable in terminating the spontaneous abortion, especially if the ovum is still in the uterus. Sufficient dilatation of the cervix and evacuation with a finger is the method of choice if this fails. The original Winter forceps is the only one permissible, and only for removing those parts which the finger can free but can not remove. A large blunt curet is useful if the finger is unable to separate the whole ovum or if only small remnants are to be removed.

Elective Action of Rays.—Seide confirms the greater injury of ascaris ova under roentgen rays when the ova are in the first stages of their development. Yet he also confirms Ruppert's observation to the contrary when using ultraviolet rays: The riper embryos were more susceptible to these than the early stages. Thus the Bergonié-Tribondeau law applies only to roentgen and radium rays.

Death from Electric Current.—Schridde made postmortems on thirty-seven men who had been killed by electric currents of not more than 220 to 250 volts. He found in thirty-six of them typical signs of a "thymic constitution": the lower extremities were long, the neck short, the skin frequently fine and pale and with only little hair, especially in the axillae, little or no beard, and a heterosexual or intersexual type of pubic hair. The thymus gland and spleen were enlarged. The only exception was one elderly man in poor general condition. Burns were not always present. In the positive cases they were on the left hand (shorter route to the heart) in 90 per cent. Therefore the old recommendation to keep one hand (the left) in the pocket while working was sensible. Edema of the lungs was present in twenty-one of his cases. The death in the remaining fifteen might be explained by fibrillation of the ventricle.

Constitution and Racial Type.—Henckel found in Sweden the same frequency of a leptosomatic (asthenic, slender) and muscular (broad) and dysplastic type in schizophrenia, and of the pycnic type in cyclic psychoses as elsewhere in Europe. Therefore the explanation of the constitutional types as racial types is not correct. He found no disturbance of correlation of external characters, such as the color of hair and eyes, in his material.

Skin Test in Inguinal Lymphogranuloma.—Frei obtained a skin reaction with an antigen prepared from the pus from the bubo in nine cases of so-called inguinal lymphogranuloma. The complement fixation tests with the serum from these patients were negative.

Antiserums to Monogenous Antigens.—Friedberger and Ikeda observed the formation of two rings in precipitation tests for serum. The upper consists of fine floccules which turn black under the action of osmic acid. The lower consists of heavy floccules which are not lipoid. They believe that nobody, including themselves, had observed the formation of two rings before. They explain the upper ring as due to heterogenous antibodies. It can be prevented by treating the serum with any boiled protein. A heterogenous antigen or toxin causes only the formation of one ring, they say.

Hemorrhages in Coma Treated with Insulin.—Ehrmann and Jacoby observed hemorrhages, especially in the brain and lungs, in twelve cases of diabetic coma, treated with large or small doses of insulin. In five of these patients, spasms of the face or extremities were probably due to the hemorrhages. Four of their patients had complained of colic in the mesogastrium.

Specific Dynamic Action of Proteins.—Liebeschütz-Plaut points out that the specific dynamic action of the proteins begins only after their resorption. A deficient function of the stomach delays it. She rates its average at 30 per cent. of the basal metabolism, and less with increased basal metabolism. She is inclined to explain Pollitzer and Stolz' results by their faulty technic.

The Blood in Cyanid Poisoning.—Hasselmann found a moderate polycythemia in people employed in the manufacture or handling of hydrocyanic acid. The number of leukocytes with basophilic granulation was increased in some of them.

Acetonemia in Pregnancy Toxicosis.—Bokelmann and Bock had found an increased amount of acetone in the blood in pregnancy. It was especially high in toxemia.

Thoracic Herpes Zoster and the Stomach.—Hess and Faltitschek observed hypermotility and hypersecretion of the stomach in patients with herpes zoster of the thoracic segments—especially of the lower ones. The gastric disturbances disappeared together with the eruption.

Local Chilling in Disease in Parietal Lobe.—Wodak induced a past-pointing reaction by chilling of the skin over the parietal lobe in a patient with an operative defect of the bone in that region.

Fixation of Bacteriophage on Bacteria.—Kimura reviews the experiments on fixation of bacteriophages by living and killed bacteria. The specific antibacteriophage serums prevent their fixation on the germs. The affinity of the serums for the bacteriophage is weaker than the affinity of the bacteriophage for the germs.

Precolumbian Syphilis in the Near East. P. Hildebrand.—p. 1928.

Roentgen Irradiations in Syphilis.—Wirz observed four syphilitic patients who had been subjected to treatment with roentgen rays because of a blunder in diagnosis. One of them was thus mistreated in the primary stage (a virgin with chancre of the tonsil acquired at a kissing game); the three others were in the tertiary stage. The syphilis was grave and relatively refractory to treatment in all of them. The rays had been applied to the cervical lymph nodes, the skin or the lip.

Influencing the Insensible Perspiration.—Moog and Eimer found a decrease of the insensible perspiration after intravenous injections of 10-20 c.c. of a 10 per cent. solution of sodium chlorid; an increase after 10 c.c. of a 10 per cent. solution of calcium chlorid and a delayed decrease after intramuscular injection of 5 c.c. of a 50 per cent. solution of cane sugar.

Treatment of Atrophy of Pigment. — Axmann utilizes Freund's observation on the photosensitizing action of eau de cologne in phototherapy of vitiligo.

The Misshapen Foot in Civilization.—Fischer attributes the frequency of deformities of the foot in the Western nations to six causes: the premature teaching of children to walk, the training to turn out the toes, outward rotation of the foot, the unphysiologic manner of walking, the unnecessary and excessive standing, and the incorrect way in which shoes are made. He discusses the latter nuisance in detail, and describes his device for obtaining the correct shape of the shoe to fit the foot.

Pathology and Treatment of Leukorrhea. Novak. Supplement.—pp. 1-12.

Peptone Therapy.—Pollitzer found in intramuscular injections of from 2 to 5 c.c. of a 5 per cent. solution of peptone a good antidote against the diarrhea following injection of novasurol. He had favorable results with it in a case of colitis, and in hemoptysis. The excellent effect in asthma is also confirmed.

Chemotherapy.—Saxl, Donath and Kelen protected rabbits by injections of acriflavin and other substances against a subsequent infection with lethal doses of colon bacilli.

Function of Suprarenal Cortex.—Falta concludes that the cortex of the suprarenals exerts a strong influence on the growth of the body, the sex organs, and especially on the secondary sex characters (virilism in women, hypervirilism in men). The latter occurs even with dystrophy of the gonads.

Endocrine Relations Between Mother and Fetus.—Neurath's patient, a mother of two healthy children, had been subjected to partial thyroidectomy for goiter. Ten months later a child with goiter was born, in an asphyxiated condition, and died. Experiments on rabbits have failed to date, because gestation did not take place in his thyroidectomized animals.

Hypnosis Combined with Narcotics.—Schilder administers to the patient from 0.5 to 1 gm. of barbital two hours before the intended hypnosis, and keeps him from sleeping. Paraldehyd in doses of from 4-10 gm. or amylene hydrate, 4-6 gm., act rapidly, and the hypnosis can be started in a few minutes. Overdoses prevent the rapport by producing real sleep.

*Second Infection with Measles. B. de Rudder.—p. 289.
*Feeding Cod Liver Oil to Cows. R. Wagner and H. Wimberger.—p. 295.

Vitamins and Pasteurization of Milk.—Blumenberg found a low vitamin C content in cow's milk.

ished by pasteurization. Half an hour at 63 C. is worse than one quarter of an hour at 85 C. A rapid heating of pasteurized milk just to the boiling point does not impair it any more.

Caronia's Measles Prevention.—Nobel and Schönberger found that Caronia's vaccine used early may protect against measles. They do not claim that the protection is specific. They observed on the ninth and tenth day after the vaccination of the children symptoms which might perhaps be regarded as rudimentary measles.

Diuresis Test After Concentrated Feedings.—Baumecker and Schönthal made diuresis tests on infants fed with concentrated food. One group retained water after even a short period of the thick feedings, another group after a prolonged period, and a third not at all. This third group gained steadily in weight on this diet; the second only temporarily, while the first group responded by losing in weight immediately.

Familial Polycythemia.—Kretschmer observed polycythemia of the Vaquez type in three children in one family (two sisters and one brother).

Whey and Blood Sugar.—Keilmann found that whey retards the hyperglycemia from milk sugar. Casein does not influence it. The action of whey may be due to an inhibition of resorption from the bowel.

Whey and Lactosuria.—Bernhard found that lactosuria occurs with whey with smaller amounts of lactose than with deproteinized whey or water.

Whey and Acute Diarrhea.—Finkelstein concludes from the series of studies made by himself and his collaborators that whey favors abnormal bacterial processes in the intestine. He believes that the reduction of whey in "albumin milk" is an important therapeutic factor.

Second Infection with Measles.—Rudder reports on a child who had measles twice—the diagnosis being as certain as can be required by extreme skepticism.

Feeding Cod Liver Oil to Cows.—Wagner, Wimberger and their collaborators found no increase in the antirachitic value in milk of cows fed for several months with the addition of from 50 to 300 gm. of cod liver oil. Neither was the vitamin A content increased.

*Agglutination and the Bacteriophage in Typhoid. J. Stolz.—p. 1588.
Cleaning of Vaccine Virus. K. Urbánek.—p. 1591.

Spasms of Constrictors of Larynx.—Cisler observed in dogs poisoned with atropin a spasm of the constrictors of the larynx, with the exception of the arytenoid muscles. The only corresponding case in man had been observed by Wiškowský in a neurotic patient.

War Experiences on Getting Chilled.—Pelikán describes his experiences in Russia. In spite of extremely cold weather and sudden changes of temperature (feet near the hot stove and head at the periphery of the car with zero temperatures), there were no diseases attributed to colds. This was observed even on a transport carrying 1,000 insufficiently equipped soldiers for a distance of 4,000 kilometers. Later on, with a sudden change to a tropical climate on the boat, the soldiers exposed themselves freely to drafts. No diseases occurred.

Sequels of Cervical Sympathectomy.—Jirásek observed a hemorrhagic pleurisy, atony of the esophagus and trigeminal neuralgia after extirpation of the cervical sympathetic in a patient with angina pectoris. The pleura had probably been directly injured during the exeresis of the nerve. Irritation of the sympathetic explains the other symptoms.

Agglutination and the Bacteriophage in Typhoid.—Stolz found that the presence of the bacteriophage in the blood does not interfere with the agglutination occurring within two hours. If the flakes become dissolved within forty-eight hours, the bacteriophage is present, and the prognosis is good.

68: 841-864 (Sept. 10) 1925

*Kidney Tests with Prostatic Obstruction. V. Eskelund.—Begun p. 827.
*Collodion Membranes. Lundsgaard and Holbøll.—p. 849. C'cn, p. 865.

Kidney Function Tests with Hypertrophied Prostate.—Eskelund investigated the influence on the composition of urine and on the diuresis of effectual drainage (retention catheter) in seven cases of prostatic obstruction. In one case the Ambard coefficient and the urea content of the blood showed great improvement, but the excreted thiosulphate dropped from 16.3 to 9 per cent. in a week. Notwithstanding these conflicting findings, the enlarged prostate was removed. The man died from uremia the eleventh day, and the right kidney was found almost totally destroyed with a carcinoma. The urine of only one of the eight patients was still sterile after six days of catheterization; two had been infected beforehand. If drainage is free, the infection is restricted to the bladder, but it extends to the pelvis if the catheter gets obstructed. The thiosulphate test seems especially instructive in estimation of kidney functioning in acute retention, in which the urea content of the blood is more the expression of a temporary suspension of the catabolyzing function rather than of the actual functional capacity of the kidneys.

Standardization of Collodion Membranes.—The membranes were placed in solutions of alcohol of different concentrations, to produce different grades of permeability. The diffusion coefficient drops as the concentration of the alcohol increases. By the simple technic described, collodion membranes can thus be standardized.

68: 865-888 (Sept. 17) 1925

*The Sedimentation Test. I. Freuchen.—p. 871.

The Sedimentation Test.—Within certain limits the diameter of the tube is immaterial for the outcome of the sedimentation test. The reading is most instructive at the half hour and the hour. Freuchen found that ten drops of the 3.5 per cent. sodium citrate solution gave the best results using a glass of 13 mm. diameter, of a capacity of 7.5 c.c. The highest figure he obtained was in a man with pernicious anemia; the figure was 39.5 at the half hour and 42 at the full hour. In blood from twenty horses, tested minute by minute, the greatest differences between the sick and the well were observed at the eleventh minute, sedimentation occurring much more rapidly in horse blood than in human blood.

*Picric Acid Dermatitis. J. Foged.—p. 889.
*Conservative Versus Operative Treatment of Salpingitis. Andersen.—p. 901.

Picric Acid as a Disinfectant for the Skin.—Foged warns that a universal and protracted dermatitis developed in four of the fifty-two cases in which he used a 5 per cent. alcoholic solution of picric acid for local disinfection of the skin, mostly before major operations. In all the other cases the effect was excellent, confirming the efficacy of picric acid for this purpose.

Salpingitis.—Andersen states that operative treatment of nontuberculous salpingitis gave by far the best results in 500 cases treated by various methods in Rovsing's private clinic or public hospital service. The ultimate outcome has been better in the operative grave and medium cases than in the conservatively treated mild cases.

Vol. 85, No. 26 Chicago, Illinois December 26, 1925

THE CLINICAL DIFFERENTIATION OF SPONTANEOUS INTRACEREBRAL HEMORRHAGE AND UREMIA

A FOURTH STUDY OF COMA*

E. R. LeCOUNT, M.D.
AND
C. C. GUY, M.D.
CHICAGO

In 1915, one of us (E. R. L.) took part in a report[1] designed to help hospital interns and residents in recognizing the causes of coma so frequently dealt with by them as emergencies, especially in large urban hospitals. This was followed by two subsequent reports.[2]

These three reports concern 746 deaths, all with necropsies, and emphasize the infrequency of uremia as a cause of coma and the need for giving due value to the time under observation as an important factor in any discussion of errors in diagnosis. They do not, however, mention the importance of another factor, that death soon after entrance often prevents the examination and study of a puzzling coma by the more experienced attending staff, although in Holcomb's article,[2] this is suggested in a comment on the difference between the correctness of diagnoses made in the examining room and those subsequently made in the wards.

The present report has to do with a much smaller number, only thirty, and is limited to difficulties in distinguishing between spontaneous intracerebral hemorrhage and uremia, and to illustrating the value of the chemical examination of the blood for this purpose.

In the last four years (1921 to 1924, inclusive) at the Cook County Hospital, there have been thirty patients on whom chemical examinations of the blood were made, and death was found at necropsy to be due to spontaneous intracerebral hemorrhage. In nine of these (Group A), the clinical diagnosis was uremia, uremic coma or chronic nephritis; and in only three of these nine was cerebral hemorrhage or thrombosis mentioned as a possibility. For the remaining twenty-one (Group B), the diagnosis spontaneous intracerebral hemorrhage was correct in sixteen; and in five of these twenty-one, the incorrect diagnoses were skull fracture (two), poisoning, meningitis and diabetic coma. Thus, as shown in the accompanying chart, 53 per cent. of the diagnoses were correct, which may be compared with the 51 per cent. in 1915 and the 64 per cent. in 1921 in the reports mentioned.

The length of stay in the hospital for these thirty patients varied from an hour to twenty-two days, the average being about four and one-half days, so that there was usually sufficient time for the study of the illness. The relation between the time in the hospital and the accuracy of the diagnoses is graphically shown in the chart.

There were twenty-four men and six women, with ages from 24 to 77, averaging 51 in Group A, and 49 in Group B, which is significantly low. Nineteen patients were in coma on entrance, seven were semicomatose or stuporous, and four were conscious. In the first group, in which uremia was diagnosed, the average blood pressure was 205 systolic and 115 diastolic; the heart was enlarged in three; heart murmurs were heard in two, and definite palpable arteriosclerosis was noted in one. There was partial or complete hemiplegia in four, and in three no paralysis was found. The pupils were normal in two, and did not react to light in five. Urinalysis was done in eight, and albumin and casts were found in all of these; leukocytes were found in five, and Haines' solution was reduced in one. Wassermann tests of the blood or spinal fluid were made and found to be negative in eight; of the seven in which the spinal fluid was examined, blood was found grossly in six, and was entirely absent in one.

In the other group of twenty-one patients, the blood pressure varied from 125 to 208 systolic, and from 70 to 140 diastolic, an average of 194 and 109, respectively. In fifteen there were evidences of a hemiplegia; in three no paralysis was found. Heart murmurs were heard in two, and enlargement was noted in four. The pupils were normal in three, reacted to light in five, and did not react to light in thirteen. In seventeen urinalysis was done; albumin was found in fifteen, casts in nine and an increase of leukocytes in nine, and Haines' solution was reduced in six. The average specific gravity of the urine was 1.017. Spinal puncture of twenty patients revealed blood grossly in the spinal fluids of eighteen, a positive benzidin reaction in one, and an absence of any evidence of blood in the other. Wassermann tests were positive with two spinal fluids, but negative with the blood of one of these patients, and also negative with the blood of sixteen others so examined.

The alterations found by chemical examination of the blood[3] in Groups A and B are shown in Tables 1 and 2, respectively, and the averages of all cases in

Table 3. When the figures in these tables are compared with the averages for conditions in the blood in health and in disease (Table 4), it is evident that there is only an occasional patient in whom the increase in the substance sought in the blood at all approaches that found in uremia, and the averages for the whole series (with the exception of the blood sugar) are low in comparison with the estimates usually given for uremia. It is especially noteworthy that the averages with the illnesses wrongly diagnosed uremia are almost the same as the majority of those correctly diagnosed.

Table 1.—*Chemical Analysis (Milligrams per Hundred Cubic Centimeters of Blood) of the Blood for Nine Patients Dying from Spontaneous Intracerebral Hemorrhage with the Clinical Diagnosis of Uremia*

	Non-protein Nitrogen	Urea Nitrogen	Uric Acid	Creatinin	Sugar
Range	34.56 to 49.97	13.07 to 28.02	2.76 to 4.00	1.45 to 1.51	104 to 244
Average	38.84	18.35	3.33	1.49	178

Table 2.—*Chemical Analysis (Milligrams per Hundred Cubic Centimeters of Blood) of the Blood of Twenty-One Patients* Dying from Spontaneous Intracerebral Hemorrhage*

	Non protein Nitrogen	Urea Nitro gen	Uric Acid	Creat inin	Sugar
Range	28.0 to 64.2	7.93 to 46.7	1.58 to 3.16	1.40 to 2.50	101 to 333
Average	36.74	19.85	2.38	1.65	164
Number of cases	13	21	15	20	12

*Sixteen cases were diagnosed correctly

Table 3.—*Conditions in the Blood of Thirty Patients (Milligrams per Hundred Cubic Centimeters)*

	Non-protein Nitrogen	Urea Nitrogen	Uric Acid	Creatinin	Sugar
Range	28.0 to 64.2	7.93 to 46.7	1.58 to 4.00	1.40 to 2.50	101 to 333
Average	37.79	19.10	2.86	1.57	171
Number of cases	18	27	20	26	17
Percentage of increase above normal*	26%	19%	43%	16%	71%
Percentage of increase above normal in uremia*	733%	1,150%	775%	1,370%	50%

* Normal being the averages of the amounts of the various chemical elements of the blood in health as given in a previous reference

Table 4.—*Averages of the Chemical Examination of the Blood in Health and in Uremia**

	Mg per 100 C c. of Blood				
	Non-protein Nitrogen	Urea Nitro gen	Uric Acid	Creatinin	Sugar
Normal	25 to 35	12 to 30	1 to 3	1 to 2	100
Uremia	90 to 250	70 to 300	4 to 27	4 to 33	100 to 200

* From Myers, V C Practical Chemical Analysis of Blood, St Louis, C. V Mosby Company, 1924 p 26 Hawk, P B Practical Physiological Chemistry, Ed 8, Philadelphia, P Blakiston's Son & Co, 1923, p 273

At the necropsies, all were found to have had intracerebral hemorrhages, and free blood was present beneath the leptomeninges in eight. Edema of the brain was noted in ten, and it may be of some significance as regards the symptoms that the illness in only four of these was correctly diagnosed. In two cases the kidneys differed in no way from the normal; a passive hyperemia was noted in nine, retention cysts in four, and cloudy swelling in five. In nine they were described simply as "chronic diffuse nephritis," in seven as small red granular kidneys, in two as primarily contracted, and in two as of the arteriosclerotic type. In twenty cases, or only 67 per cent., were obvious chronic pathologic processes present in the kidneys. The heart in five was normal grossly; in twenty-one there was myocardial hypertrophy; in eleven calcification, sclerosis or other changes in the heart valves, and in six a fibrous myocarditis. The arteries were sclerotic in varying degrees in twenty-three; fatty changes only were found in three, and syphilitic aortitis in four. In one the blood vessels were normal grossly.

In 1915, Bissell and LeCount[1] brought out the mistakes in the diagnosis of the causes of coma in their report of 200 patients who entered the Cook County Hospital, and whose bodies were examined post mortem. Of these, fifty-three died from spontaneous intracerebral hemorrhage, of which twenty-seven cases, or only fifty-one per cent., were correctly diagnosed. Forty-six of the 200 cases were diagnosed clinically as uremia, and in sixteen of these, or 35 per cent., death was the result of cerebral hemorrhage, and in only eight, or seventeen per cent., of uremia. In a similar article[2] in 1917, the same authors published reports of 200 additional patients who entered in coma and died; of the entire 400, death in ninety-five was due to cerebral hemorrhage, and in nineteen to uremia, indicating that in this class of patients the relative frequency of death due to cerebral hemorrhage to that from uremia is about 5 to 1.

In the diagnosis of spontaneous cerebral hemorrhage many so-called "focal" symptoms have been observed, as, for instance, those emphasized by Cumston,[4] dilatation of the pupil, papilledema, ptosis of the upper lid, corneal anesthesia and conjunctival hyperemia, all on the side of the lesion; but these are also often found on the side opposite the hemorrhage, and some of them may be observed in uremia, so that their value is not great. The blood pressure is usually high in both conditions except in the terminal stages. Shaw,[5] in a study of essential hypertension (hyperpiesia), came to the conclusion that all the manifestations of this condition are also encountered in uremia, and that the symptoms of hyperpiesia which simulate uremia are produced by toxins present in the blood as the result of some extrarenal inflammation, rather than to metabolites retained because of disorders of the kidneys. This author and O'Hare[6] have each described a case in which there were clinically high blood pressure and myocarditis (?), and the necropsies revealed spontaneous intracerebral hemorrhage with no renal disease. Williams[7] concludes that there is no relation between the blood pressure and the nonprotein nitrogen of the blood, and that arterial hypertension with normal nonprotein nitrogen blood values and normal kidney excretion does not justify the clinical diagnosis of chronic nephritis. This is of significance because with coma of obscure origin, when there is evidence suggesting a chronic nephritis, it certainly is true that altogether too frequently the results of the chemical examination of the blood are disregarded, and the coma is considered uremia.

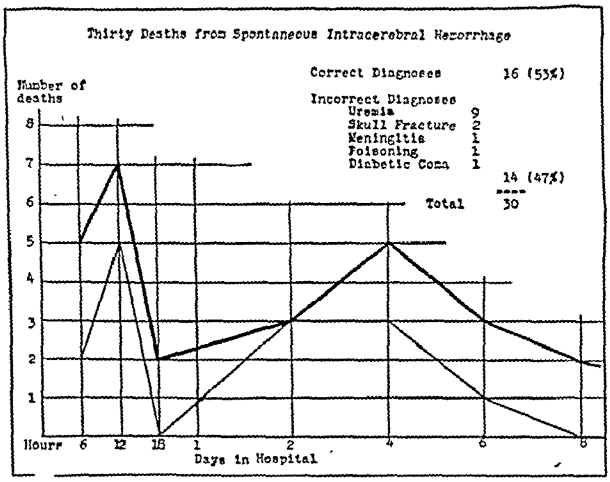
The presence of albumin and casts in the urine is usually and correctly interpreted as evidence of renal disease, or, as Senator[8] has said, "the more closely the kidneys are examined in cases of albuminuria, the oftener are structural changes found," but "it has been noted by a large number of observers that in various pathologic conditions of the nervous system, such as epilepsy, delirium tremens, various psychoses, cerebral apoplexy, nervous exhaustion, migraine, and Basedow's disease, transient albuminuria occurs with or without hyaline casts and sometimes with casts alone, and this in cases where there is no chronic renal disease or passive congestion of the kidneys such as may occur in convulsions." The transient albuminuria occasionally occurs in healthy persons following simply excitement.

Blood is usually found in the spinal fluid with intracranial hemorrhage, but may not be present when the lesion is deeply located. However, if the fluid is examined about three days after the "stroke," it usually has a canary-yellow color which often persists for months, although the ordinary tests for blood remain negative.[9]



Correct and incorrect diagnoses in thirty deaths from spontaneous intracerebral hemorrhage: Heavy line, deaths; light line, number correctly diagnosed. Three deaths not plotted occurred: one on the twelfth, and two on the twenty-second day; two of these were correctly diagnosed.

Volhard and Fahr[10] believe that the name uremia should be applied only when symptoms are observed of true urinary poisoning with definite evidence of serious impairment of the kidneys, the diagnosis to be made from the symptoms and results of laboratory studies. According to McElroy,[10] such laboratory examinations demonstrate a "marked retention of the residual blood nitrogen and urea, a low specific gravity of the night urine, a low fixed specific gravity of the day urine, low salt and nitrogen concentration, a low phenolsulphonephthalein excretion, a low urea index, a high Ambard coefficient, and increased osmotic tension[11] of the blood. But in addition to these more or less typical pictures, there is a smaller number of cases in which functional kidney tests give very variable results in the different manifestations of uremia. In the convulsive attacks associated with the acute and second stage of diffuse glomerulonephritis, and . . . with the hypertension of sclerotic conditions, there is usually very little evidence of kidney insufficiency as indicated by the tests now generally used. In such cases, the nonprotein nitrogen and urea in the blood are within normal limits." These two constituents of the blood are usually in about the relation of 2 to 1; that is, the urea nitrogen constitutes about 50 per cent. of all the nonprotein nitrogen of the blood in health, whereas with retention such as is observed in the so-called chronic interstitial nephritis, the urea nitrogen may be as much as 75 or 80 per cent.

CONCLUSIONS

The following conclusions pertain simply to the condition observed in this series of thirty deaths from intracerebral hemorrhage:

1. No patient dying from intracerebral hemorrhage with the clinical diagnosis of uremia had a nitrogen retention comparable to that of true uremia.
2. In spontaneous intracerebral hemorrhage, the increase above the normal of the various nitrogenous elements of the blood varied from 16 to 43, the creatinin (16 per cent.) being the least increased, and the uric acid (43 per cent.) the most.
3. In 67 per cent. of the thirty, the gross changes in the kidneys indicated some chronic disease; in 7 per cent., no gross changes of any kind were found.
4. The presence of blood in the spinal fluid and the great increase in the nitrogenous elements in the blood are apparently the two most important factors in the differential diagnosis between uremia and spontaneous intracerebral hemorrhage.

Med. **100**: 363, 1924), who have found that lessened osmotic pressure of the blood due to alterations in the protein content ("hypoonkie") is a specific symptom of nephritis with edema.

TREATMENT OF SEPSIS WITH MERCUROCHROME-220 SOLUBLE

REPORT OF NECROPSIES IN FIVE CASES *

A. V. ST. GEORGE, M.D.
Assistant Director of Laboratories, Bellevue and Allied Hospitals
NEW YORK

In the last few years a new antiseptic, mercurochrome-220 soluble, has been placed on the market, and considerable literature extolling its virtues has accumulated. Only two or three meager articles have come to my attention reporting unfavorable symptoms following the intravenous administration of this preparation and advising more caution and control in its application.

During the past year the following five cases, in which mercurochrome was administered intravenously during life, came to necropsy in the chief medical examiner's department of the city of New York, and showed, among other anatomicopathologic changes, the lesions of mercurial poisoning:

Case 1.—*History.*—Mrs. A. S., aged 36, white, was admitted to the hospital, March 31, 1924, with a history of having had the uterus opened to induce abortion, and of taking a large amount of various abortifacients. The chief symptoms, on admission, were pain in the lower part of the abdomen, vaginal bleeding, nausea and fever; the temperature on admission was 102 F.; the pulse, 96. Blood examination revealed white blood cells, 14,800; polymorphonuclears, 87 per cent.

---

* Read at the Thirty-Seventh Annual Meeting of the American Association of Genito-Urinary Surgeons, Washington, D. C., May 4, 1925.

* From the pathologic laboratories of Bellevue Hospital, Dr. Douglas Symmers, director, and the Office of the Chief Medical Examiner of the City of New York, Dr. Charles Norris, *chief medical examiner.*

April 3, the blood culture was positive for *Streptococcus hemolyticus* (2 colonies per cubic centimeter). Gentian violet was administered without beneficial effect. Blood cultures were positive for *Streptococcus hemolyticus,* April 13, 19, 24 and 28, there being, respectively, 6, 10, 14 and 20 colonies per cubic centimeter. April 25, 35 c.c. of a 1 per cent. solution of mercurochrome was administered; similar quantities were given, May 9 and May 11. May 12, 20 c.c. was administered, and again, May 14, 35 c.c.. No change was apparent following the administration of mercurochrome, either in temperature or in the course of the illness, save for a discoloration of the skin. The urine at various times contained albumin, pus and red blood cells. Death occurred May 15.

Necropsy.—The peritoneal cavity contained about 50 c.c. of dark straw-colored fluid. The left pleural cavity was about one third filled with free, bloody, serofibrinous fluid. The kidneys were large and swollen; on section, the cortex was very pale and the medulla deeply injected; the capsule was free, the surface smooth and pale yellowish; the pelves, ureters and urinary bladder were normal. There were extensive adhesions about the loops of the small intestine opposite the lower right abdominal quadrant, where it was firmly attached to the wall. The mucous membrane of the small intestine was natural in appearance, the upper portion being filled with yellowish bile-stained fluid. The cecum and ascending colon were enormously distended with gas; the mucosa showed elevated reddish rugae and, in places, a distinct granular appearance. The mucous membrane of the transverse and descending portions showed grayish and granular areas with superficial ulcerations. The same was true of the lower portion of the rectum, namely, that portion above the anal canal (suggestive of mercuric chlorid). The other organs showed nothing worthy of note.

The anatomic diagnosis was: serohemorrhagic pleuritis (left); collapse of the left lung; splenomegaly; infarction of the spleen; necrosis of the spleen; ulcerative and exudative colitis; acute parenchymatous nephritis; parenchymatous degeneration of the viscera; sepsis.

On histologic examination, the kidneys showed degeneration of the renal parenchyma, with hemorrhage, fatty infiltration and calcium deposits in the descending tubules. The ulcers in the intestine showed necrosis of the surface epithelium, with round-cell infiltration at the margins and diffuse edema and hemorrhagic extravasation.

Case 2.—*History.*—Mrs. M. A., aged 26, colored, who was admitted to the hospital, June 7, 1924, had had an abortion performed three weeks prior to admission. The patient developed pain over the lower part of the abdomen, chills and fever. On admission, her temperature was 102 F.; pulse, 104; respiration, 24; the blood culture was sterile; albumin and a few pus cells were found in the urine. June 11, 20 c.c. of a 1 per cent. solution of mercurochrome was given intravenously, after which the patient developed severe diarrhea, lasting two days, and albumin, pus, casts and blood cells were present in the urine. June 17, 20 c.c. of a 1 per cent. solution of mercurochrome was administered intravenously; the patient at once developed severe chills, and shortly thereafter diarrhea, which persisted until death, June 18. The blood culture at this time was sterile.

Necropsy.—The pelvic cavity showed a small amount of purulent material with a few flakes of fibrin, and the lower portion of the ileum showed discolorations and soft areas covered by fresh fibrin. The abdominal cavity contained a small amount of fluid, which was slightly cloudy and tinged yellow. The liver weighed 2,080 gm.; a cut section showed small yellowish mottled areas, suggestive of focal necroses. The gallbladder contained dark greenish, ropy bile, and the mucous membrane was normal. The kidney capsule was stripped with some difficulty. The surface was studded with small hemorrhages. The kidney substance was mottled; the markings were very irregular and the pyramids slightly violaceous. The pelves and ureters showed no changes. The combined weight of the kidneys was 360 gm. The uterus measured 3½ by 2⅝ by 1⅝ inches. On section, the mucous membrane was covered with a blood clot and was injected; the sinuses were somewhat enlarged, but there was no evident perforation. The stomach was normal. The small intestine was normal as far down as the last half of the ileum, where there were injected areas. The last foot of the ileum showed distinct ulcers, covered with greenish slough, and the wall of the ileum was thickened. The upper portion of the large intestine and the lower portion of the sigmoid showed petechial hemorrhages. The rectum presented ulcers similar to those found in the ileum; namely, irregular, serpiginous ulcers, covered by greenish slough. The other organs showed nothing of interest in the present connection.

The anatomic diagnosis was: septic pelvic peritonitis secondary to abortion; ulcerative enteritis and colitis; cardiac hypertrophy; bronchopneumonia; acute diffuse nephritis; sepsis.

Histologic examination of the kidney showed intense parenchymatous degeneration, with necrosis, round-cell infiltration, hemorrhage and edema. The intestine showed necrosis and degeneration of the surface epithelium, and replacement by edematous and necrotic slough. The deeper portions of the intestinal wall were edematous and showed dense collections of nuclear débris and, in places, hemorrhagic extravasation.

Case 3.—*History.*—M. M., a white woman, was admitted to the hospital, Sept. 24, 1924, with a diagnosis of septic abortion (spontaneous) ten days before admission, followed by chills, fever and abdominal pain. September 25, 20 c.c. of a 1 per cent. solution of mercurochrome was given intravenously at 8 p. m., followed by chill and a rise of temperature to 104.6 F., with a subsequent fall to 101.4 F.; four very loose stools were passed during the night. September 26, at 8 p. m., 1 c.c. of typhosus serum was given intravenously for foreign protein, followed by chill; an alcohol sponge was given. The temperature dropped to 99.6 F. within a few hours. Previous to September 27, the patient had been irrational and semicomatose, but on that day, for the first time, she was conscious and talked intelligently. At 7 p. m. of the same day there was a sudden onset of coma, with frothing at the mouth; the left pupil was widely dilated, the right not markedly so, both pupils reacting to light; the knee jerks and elbow reflexes were equal and active. The patient died within one hour, without regaining consciousness. A blood culture taken, September 25, previous to the administration of mercurochrome, was sterile; another, taken, September 26, after mercurochrome therapy, was likewise sterile. September 26, the stools showed the presence of blood. The urine contained pus and blood, but no casts.

Necropsy.—The pericardial cavity contained yellowish, cloudy fluid. The parietal and visceral layers of the pericardium were rough and covered with a shaggy exudate. The kidneys were large, weighing 410 gm.; the capsule was stripped with some difficulty; the cortex was wide and pale; the pyramids, violaceous; the pelves and ureters were stained yellowish but were otherwise normal. Watery, blood-stained fluid was present in the large intestine, the mucous membrane being markedly injected in some places, other portions showing raised, greenish gray ulcerations and marked thickening of the bowel and the whole being stained reddish. The scalp, calvarium and meninges were normal. The left hemisphere was much softer than the right, and the markings between the gray and white matter were not as sharp as on the right side. Careful search revealed a formed embolus in the middle cerebral artery on the left side, just above the bifurcation of the carotid and anterior to the middle third. The base of the skull was normal. The other organs showed nothing of interest in the present connection.

The anatomic diagnosis was: embolus, left middle cerebral artery; acute septic valvulitis, involving the aortic valve; anemic infarct of the heart muscle; anemic infarct of the left kidney; septic spleen; parenchymatous degeneration of the heart muscle, liver and kidney; ulcerative colitis; septic endometritis; corpus luteum, left ovary; acute pericarditis; pyopericardium; mercurochrome staining of the viscera; sepsis.

On histologic examination, the kidneys showed a diffuse parenchymatous degeneration, with fat deposition and extensive calcium degeneration of the descending tubules. The colon showed superficial ulcerations with epithelial necroses and an edematous slough. The remainder of the wall showed intense edema, hemorrhagic extravasations and granular débris.

CASE 4.—*History.*—T. P., a white man, was admitted to the hospital, Nov. 1, 1924, in delirium, with an infected right hand, spasticities, a temperature of 103.2 F., pulse 96, and respirations 26. The urine contained albumin and a few hyaline casts, but no pus or blood cells. The hand infection was treated by incisions and drainage; a culture of the wound showed the presence of streptococci. November 4, blood culture was positive for streptococcus, and on the same day 20 c.c. of a 1 per cent. solution of mercurochrome was administered intravenously, followed in one and one-half hours by a severe chill and an elevation of temperature to 105 F. On the following morning, the temperature receded to 101.2 F. and severe diarrhea developed, which persisted until death, November 19. The patient's general condition showed no improvement. He presented quite marked puffiness of the eyelids and the urine gave a marked reaction for albumin, many hyaline and granular casts, and numerous pus and blood cells. November 15, 20 c.c. of a 1 per cent. solution of mercurochrome was given intravenously, the reaction on this occasion being less marked than on November 9. November 17, the blood culture was positive for streptococci (from 20 to 30 colonies per cubic centimeter of blood).

Necropsy.—Externally there were no injuries, except for two operative incisions on the dorsum of the right hand. The deep tissues were necrosed, and the muscle was deep red and infiltrated with pus; no thrombosis was noted in the surrounding vessels. The right pleural cavity contained purulent fluid, and the right lung was covered with fresh fibrin over the base, and was injected; the cut surface was congested. The left lung was free and the cut surface normal, except for three or four small abscesses on the surface. The pericardial sac was distended by purulent fluid, and both the parietal and visceral layers of the pericardium showed a shaggy membrane. The valves were normal; the musculature was normal, except for a small abscess cavity in the fat of the apex, not involving the muscle; the fossa ovalis was closed. The kidneys were large and swollen; the markings were somewhat obscured. The cortex was pale yellowish pink, and the pyramids were deep purplish red; the pelves were injected. The esophagus was normal. The stomach contained yellowish fluid. The mucous membrane was normal. The small intestine contained the usual chyme; the mucous membrane was normal. The large intestine contained fluid greenish material; the mucous membrane from the ileocecal valve through to the rectum showed superficial ulceration and necrosis, resembling mercuric enteritis. The brain showed a purulent exudate covering both hemispheres, most marked on the left side and extending into the medulla and spinal cord; smear of the pus showed many streptococci. The other organs showed nothing of interest in the present connection.

The anatomic diagnosis was: acute suppurative pericarditis; acute suppurative pleurisy (right side); acute suppurative meningitis; abscess of the lung and pericardium; cellulitis of the right hand; acute ulcerative colitis; acute nephritis.

On histologic examination, the kidney showed intense parenchymatous degeneration, marked injection of the vessels, fatty infiltration of the cells and some calcium degeneration. The colon showed erosions of the epithelium, localized ulceration and edema, and degeneration of the submucosa and muscularis, with extensive nuclear débris.

CASE 5.—B. G., a white woman, aged 36, was admitted to the hospital, Nov. 17, 1924, with the diagnosis of septic abortion, resulting from the self-introduction of an orange-wood stick six days prior to admission. During her stay in the hospital, the temperature ranged from 104 to 105 F., the pulse from 105 to 130, and the respirations from 26 to 48. The white blood cells numbered 15,600; polymorphonuclears, 88 per cent. The urine contained albumin, an occasional cast and pus cells. November 18, the blood culture was positive for *Streptococcus hemolyticus* and *Staphylococcus aureus.* November 19, 20 c.c. of a 0.5 per cent. solution of mercurochrome was given, and on the following day a similar amount was administered. Blood culture taken after the latter injection was still positive, and the urine contained albumin, pus, many casts and red blood cells.

The patient died, Novemebr 21.

Necropsy.—Puncture wounds were noted in the left and right cubical fossae, under the breasts. The vaginal orifice was wide, admitting three fingers with ease; a brownish discharge escaped from it. Milk could be expressed from the breasts. On section, no free fluid was present in the peritoneal cavity; the diaphragm reached the fourth rib on both sides. The heart weighed about 400 gm.; the pericardium showed a number of petechial hemorrhages. The mitral valve was thickened from an old mitral valvulitis and, in addition, showed fresh vegetations; the rest of the valves were normal; the fossa ovalis was closed. The spleen was large, weighing 300 gm.; on section it showed a large infarct, with softening in the center of the infarct. The kidneys were large, weighing 428 gm.; the capsule was stripped with some difficulty. The surface was studded with small abscesses, surrounded by hemorrhagic zones. On section, the cortex was pale yellowish, with deeply injected medulla; the pelves and ureters were normal. The uterus measured 4 by 3 by 2½ inches; there were two grayish punctate marks on the anterior lips of the cervix, probably tenaculum marks. The tissue of the internal os was greenish and necrotic. In the cavity of the uterus was a placental site on the superior wall, covered by a fresh, green, necrotic slough. The walls of the uterus were thick and the sinuses dilated. The left ovary showed a large corpus luteum cyst, measuring 1 inch in diameter, filled with clear fluid and surrounded by a lutein zone, ⅛ inch in diameter. The stomach contained brownish fluid; its mucous membrane was normal. The small intestine contained the usual chyme and feces; the mucous membrane was normal throughout, except for punctate hemorrhages here and there. The cecum was intensely injected, hemorrhagic and stained yellowish red; the lower colon showed a half dozen superficial ulcerations. The other organs showed nothing of interest in the present connection.

The anatomic diagnosis was: acute and chronic mitral valvulitis; infarcts of the spleen; septic endometritis; acute colitis; acute nephritis; miliary abscesses of the kidneys.

Histologic examination revealed a slough over the erosions in the colon, edema, some polynuclear and round-cell infiltration, and hemorrhage. The kidneys showed parenchymatous and fatty degeneration, focal abscesses and marked congestion.

COMMENT

These five cases represent the first of a series that came under observation in the chief medical examiner's office. Since these cases all showed strikingly similar lesions, both in the kidneys and in the colon, the chief medical examiner has performed postmortem examinations on all cases reported to his department in which mercurochrome has been used, with the result that he has accumulated a series of twelve cases, all of which showed evidence of renal and colon involvement.

In the five cases here presented, it is our opinion that mercurochrome induced the intense nephritic and intestinal lesions and thus contributed to death. Chemical analysis of all the viscera in these cases, made by A. O. Gettler,[1] pathologic chemist to Bellevue Hospital and toxicologist to the chief medical examiner of New York, showed mercury in even larger amounts than were found in mercuric chlorid poisonings, a fact indicating the marked toxicity of this drug and justifying the opening statement.

It may be argued that cases have been reported in which the drug was used successfully, although a temporary nephritis and colitis did accompany its use, and hence the lesions could not be of moment. To this, it may be answered that in cases of mercuric chlorid poisoning with nonsecreting kidneys and severe colitis patients do recover and the kidney and the colon are apparently restored to normal, though subsequently these cases show a chronic nephritis, a factor that has not as yet been determined in mercurochrome cases.

---

[1] Gettler, A. O.: To be published.

From the meager cautioning literature, and the unfavorable cases that are everywhere discussed but not published, it is evident that the dangers of the drug have not been brought sufficiently to the fore. Locally, mercurochrome probably is a very good antiseptic; systemically, it may possibly be of value in selected cases when properly administered and controlled, though its indiscriminate use, for example, in such conditions as acute rheumatic fever or malaria, should not be countenanced. That its dangers are constanly to be borne in mind is apparent from the foregoing case reports, in that mercurochrome in its therapeutic dose not only exhibited no curative effect, but produced lesions associated with a toxicologic agent, and the margin of safety between a therapeutic and a toxic dose must be variable and small indeed.

MANGANESE POISONING AND ITS EFFECT ON THE CENTRAL NERVOUS SYSTEM

REPORT OF SIX CASES *

R. FINLEY GAYLE, Jr., M.D.
Associate Professor of Nervous and Mental Diseases, Medical College of Virginia
RICHMOND, VA.

My attention was recently attracted to the subject of managanese poisoning when I was consulted by a patient who was suffering with a malady, the clinical picture of which was not at all familiar to me. The condition was obviously the result of a disease of the central nervous system, but it fitted no classic picture of a well recognized syndrome. In view of the fact that the patient had worked for several months in a manganese grinding plant, the possibility of manganese poisoning was considered. The descriptions available of this disease agreed so well with the subjective and objective symptoms of the patient under consideration that this diagnosis was made, but with some hesitation. Later, the wife of the patient volunteered the information that she knew of several other workers in the same manganese grinding plant who suffered similarly. Forthwith, a trip was made to the neighborhood of this grinding plant in Virginia, and five similar cases were found.

HISTORY

In looking up the subject, one is surprised that there are so few cases of manganese poisoning recorded and that so little has been written about the disease. Couper,[1] in 1837, first described the disease among workmen who handled manganese dioxid in the manufacture of chlorin for bleaching powder. The description of the symptoms of his patients was very similar to those in my series. In 1901, von Jaksch[2] described three cases that he considered atypical types of disseminated sclerosis in workmen employed in manganese grinding plants. He attributed the disease to a manganese toxicosis. Embden,[3] Friedel,[4] Seiffer[5] and Seelert[6] noted the disease and described cases similar to those already reported. Von Jaksch,[7] in 1907 and 1910, reported other cases. In all, only fifteen cases have been reported to date in the European literature.

In 1913, Casamajor[8] reported nine cases, the first ones to be recorded in America. In 1919, Edsall, Wilbur and Drinker[9] completely summarized the literature and reported in detail several of their cases. In 1922, Davis and Huey[10] added two cases to those already recorded.

With the exceptions of Couper's five cases and four of von Jaksch's, all of the cases reported have been caused by inhalation, or swallowing in the saliva, of manganese dust in grinding plants. Von Jaksch[7] states that no new cases developed when the dust was abolished, and it is his belief that the lung is the portal of entry, the manganese later entering the nervous system probably as an albuminate.

My six patients had all been in contact with an atmosphere heavily laden with fine manganese dust for periods varying from three to ten months. Not *until recently had any precaution been taken to protect* the men working in this mill. After several cases of suspected poisoning had developed, the operators of the plant had provided the workmen with masks, but as they were uncomfortable, the masks were seldom worn. Dust collectors were provided in the mill, but they were entirely inadequate to collect the dust produced in the process of grinding the ore.

PATHOLOGY

Little is known of the exact pathology of the disease. There were no postmortem examinations in any of the foreign cases; in fact, there is no report in the literature of the disease, per se, ever having been fatal. Casamajor[8] reported a necropsy on one patient with manganese poisoning who died of pneumonia. He noted no gross changes in the brain or cord but stated that he found the longitudinal fibers of the pons degenerated. Unfortunately, no mention was made in the report of this necropsy of the microscopic appearance of the corpus striatum. It is my belief, based on clinical findings and the experimental work of Mella,[11] that the central nervous system lesion of manganese poisoning is probably in this location. The similarity of the poisoning to Parkinson's disease and to Wilson's syndrome is striking. Stocker[12] states that in making the diagnosis of Wilson's syndrome (progressive lenticular degeneration) one must be careful that the patient has not worked in manganese, as the poisoning from this element strikingly resembles such a condition.

Mella,[11] in an experimental study of poisoning by manganese in monkeys, found a clinical picture that he attributed to lesions of the basal nuclei. Histologic examination in his cases showed definite changes, particularly in the corpus striatum and globus pallidus.

SYMPTOMS

The clinical picture of chronic manganese poisoning is such a striking one that, when once seen, it is hard to confuse with other diseases of the central nervous system. The initial symptom in three of my six patients was disturbance of gait and in two of the remaining patients this was the second manifestation. In each of the patients the following symptoms were invariably found: nervousness; weakness and fatigue; disturbed gait with retropulsion on arising and propulsion on walking, and causeless laughter with silly conduct and expression. Paresthesias were noted as an early complaint in four cases; intention tremor of the hands, in five; monotonous speech, in five; awkward, clumsy movements of the extremities with loss of the finer movements of the hands, in four; masked expression, in four; a loose-hanging lower jaw, in three; an infrequent, deep inspiratory sigh, in three, and lethargy, in two. Abnormal mental symptoms were observed in every patient, mostly of personality, and in only one case were intellectual aberrations observed. Irritability, lack of sociability, tearfulness and mild exaltation were the outstanding changes. Two of the patients became suspicious, without cause, of their families and friends. The organic neurologic findings were almost uniform, the gait was altered in every case, the station was unsteady and the deep tendon reflexes were increased over the normal in the majority. Intention tremor of the hands and increased muscle tone were found together with masked expression and monotonous speech. None of the patients showed pathologic plantar reflexes, objective sensory changes, atrophy or edema. The pupils were not altered in size, shape or reaction. The fields of vision were normal as well as could be detected by a rough examination. Intra-ocular examination showed definite pallor in one case and a very reddened vascular retina in another. No involvement of the cranial nerves was noted except suspicious weakness of the facial nerve in one patient and the drooping lower jaw, in three.

Peripheral neuritis is a frequent symptom of poisoning from various metals, and it is possible that there may be some neuritic involvement in these cases. This may be suspected in view of the fact that four of the patients examined complained of paresthesias of the extremities, and in two of them actual pain was described. Against this belief is the activity of the tendon reflexes, the absence of objective sensory changes and muscular atrophy, and the character of the pain.

An interesting feature of the investigation of these patients was that the operators of the grinding plant and a few people in the community were of the opinion that the symptoms were due to the drinking of corn whisky and fermenting cider. Adjacent to the manganese mill was a vinegar plant, and it was stated that the mill workers would steal the fermenting cider and become intoxicated by it. One of the patients reported here had been sent to one of the state insane hospitals as an alcoholic, and his condition while there also was thought to be due to the use of alcohol. It is a fact that, with one exception, each of these patients drank rather heavily, at one time or another, while in contact with the manganese dust. In studying the case reports, however, it will be noted that Patient 5 developed symptoms of poisoning after being in contact with manganese dust for a shorter period of time than the others; but from his own statements, from the statements of his physician and from other reliable sources, the information was gained that he had never used alcohol in any form as a beverage. There is nothing to convince me that alcohol played any part in the symptom complex here presented. Certainly, I have never observed or seen reported, either in acute or in chronic alcoholism, a description that would fit the picture of these cases.

REPORT OF CASES

Case 1.—*History.*—A white man, aged 35, who had been a farmer prior to working in a manganese grinding plant, where he was employed from March until December, 1924, was in constant contact with the manganese dust and not until September did he wear a mask for protection. His family history was negative except that one brother had symptoms similar to those of which the patient complained, and he also had worked in the same manganese plant.

The past history was negative except for a slight attack of influenza in 1918, and there was no record of venereal disease. The patient's habits were good except that he had not slept well since working in manganese and during this time he drank corn whisky rather heavily. In July, 1924, he first noticed that he was nervous, unable to sleep, and had a sense of falling forward when walking, and on arising had a tendency to stagger backward. There were paresthesias in the arms and legs, and aching pain in the right arm and leg. He developed a slow, monotonous speech, and there was some loss of the fine movements of the hands, more noticeable on the right. The patient developed tremor of the hands, which was more perceptible on movements of intention. His memory was impaired; he became mentally confused at times, was silly, was constantly smiling and would laugh without cause. Occasionally there was vertigo. The general physical examination was entirely negative except that he showed evidence of pyorrhea alveolaris.

Neurologic Examination.—The patient had a slight sway in station, showed a tendency toward propulsion in walking and noticed that the movement of the right leg was awkward. On arising, he would tend to fall backward. The deep reflexes were exaggerated, and there were no pyramidal tract signs. There was a fine tremor of the extended fingers and definite intention tremor of both hands; sensation was normal. Speech was slow and monotonous, and there was a masked, stolid expression. The pupils were equal, regular and reacted promptly; there was no nystagmus. The cranial nerves were intact. The fundi showed no changes, and the vision fields were not restricted, as tested by rough examination.

At the time the patient left the manganese plant, his wife stated that he showed definite confusion. He was asocial, listless, could not sleep, dreamed a great deal and frequently would scream out in his sleep. He was emotionally disturbed and this was manifested by tearfulness, irritability and a constant, causeless laughter. At the time of examination, he showed no mental symptoms other than silliness, tearfulness, lack of sociability and the causeless laughter.

Case 2.—*History.*—A youth, aged 18, whose family history and past history were relatively unimportant, had worked in a manganese grinding plant where he was in constant contact with the dust for four of the seven months (January to August, 1924) that he was employed.

Before going to work in this plant he drank heavily, but while employed there he drank considerably less. He dates the onset of his symptoms from July, 1924. The first complaints were general weakness and slowing up of the gait, lethargy, dribbling of saliva and hanging of the lower jaw. His gait became progressively worse, and he noticed that he was dragging the left leg. Shortly after this, he became very nervous. His expression became silly; he developed the typical causeless laughter and a monotonous speech. Later, there appeared an intention tremor of the hands, propulsive gait and retropulsion on standing, and frequent long inspiratory sighing. He also developed numbness and tingling in the arms, hands and feet. The general physical examination was negative except for large, infected tonsils.

Neurologic Examination.—There was slight sway in station, awkward gait with spasticity of the right leg, and a rising movement of the right heel. His posture was slightly stooped. There was exaggeration of all the deep reflexes and increase in muscle tone in both legs. No pyramidal tract signs or ataxia could be elicited. There was a slight intention tremor of both hands. The speech was slow, was monotonous and at times suggested the bulbar variety. The pupils showed no changes, and there was no diplopia or nystagmus. The fundi, vision fields and cranial nerves were normal. There was a loss of the finer movements of the hands, which was particularly noticeable in writing.

Case 3.—*History.*—A man, aged 28, night superintendent of a manganese grinding plant, was in more or less constant contact with the dust for about ten months. The family history was negative. The past history showed nothing of importance except that the patient had a mild case of influenza in 1918 and three attacks of quinsy. He had overindulged in the use of alcohol and drank heavily before working in the manganese mill, but during that time he drank considerably, though less heavily.

He dated the onset of his symptoms to August, 1924, at which time there was a slowing up of his speech. He had been working in manganese for about eight months. He then developed uncontrollable, causeless laughter, then slowing up of his gait and dragging of the feet, generalized muscular weakness, particularly in the legs, and a sense of retropulsion on arising. He became nervous and irritable, and had flare-ups of temper and a frequent sighing noise made with long inspiration. There was dribbling of saliva and drooping of the lower jaw. The general physical examination was negative except for infected tonsils and slight thyroid hypertrophy.

Neurologic Examination.—The patient showed a definitely masked expression. His station was steady, the gait was slow and awkward with a tendency to propulsion, and there was some retropulsion on arising. The deep reflexes were all exaggerated. There were no pyramidal tract signs, but the muscle tone was generally increased, the posture was stooped and the finer movements of the hands were clumsy. There was a slight intention tremor of the hands and a coarse tremor of the lips and lids. The lower jaw tended to droop. Speech was slow and monotonous, and enunciation was poor. The pupils showed no change from the normal; there was no diplopia or nystagmus. The fundi and vision fields showed no changes, and the cranial nerves were intact. Mentally, the patient revealed no memory defect; he was somewhat emotional, as shown by irritability and causeless laughter and lack of sociability. There were no other mental symptoms.

Case 4.—A boy, aged 17, with a negative family history and an unimportant past history which showed no diseases other than mild influenza in 1918 and occasional tonsillitis, said he had drunk a considerable amount of whisky during the time he was working in manganese; otherwise his habits were good.

The patient dated the onset of his illness to July, 1924. He had worked in the manganese grinding plant since January of the same year. The first symptoms noticed were lethargy and difficulty in using the legs, with marked weakness over the entire body, especially in the lower extremities. There developed staggering in walking, some headache, and the personality changes of irritability, causeless laughter and mental exhilaration with verbosity. He became nervous, had outbursts of temper, and developed a frequent sighing noise on long inspiration. Later, his gait became more involved, and there was a propulsion in walking and retropulsion on arising. There were marked tremors of the extremities, which were increased on intention, and he developed paresthesias of the extremities. A general physical examination was negative except for infected tonsils and teeth.

Neurologic Examination.—The patient had slight sway in station, slow, awkward gait and a tendency to stagger. The deep reflexes were exaggerated, and there was a general increase in muscle tone. The finer movements were clumsy; this was especially noticed in writing. There was head nodding and tremor of the legs, face and tongue and some intention tremor of the hands. There was no masked expression. Speech at the time of examination appeared normal, but his mother described a slow, monotonous speech formerly. The pupils showed no changes, and there was no diplopia or nystagmus. The eye grounds exhibited marked pallor of the optic disks, especially of the temporal halves; this appeared to be more than the normal temporal pallor. On rough examination, the vision fields showed no changes. There was suggestive left facial weakness; otherwise, no cranial nerve involvement was noted. Mental examination revealed some emotional changes, with irritability and causeless laughter. The patient was also slightly elevated, though somewhat asocial.

Case 5.—*History.*—A man, aged 47, married, and the father of three healthy children, gave a negative family history, and had never been sick prior to the time he came in constant contact with manganese dust in this grinding plant. He began work in January, 1925, and worked there three months. He wore a mask part of the time but stated that it was uncomfortable and he did not feel it necessary to protect himself.

The patient's habits were very good. He never indulged in the use of alcohol. He noticed within fifteen days after going to work in this plant that he would stagger forward or backward, and when sitting would have a sensation of falling backward and on arising would have slight retropulsion. He became nervous, irritable and, at times, happy, jovial and slightly elevated. He noticed that he became weak and would tire easily; his memory was impaired, and there were some paresthesias of the hands and feet. A general physical examination was negative except for pyorrhea alveolaris.

Neurologic Examination.—The patient had a slight sway in station, unsteady gait with propulsion in walking, and some retropulsion on rising. The deep reflexes were present but not exaggerated, and there were no pyramidal tract signs, no change in muscle tone, no incoordination. The skin reflexes were active and equal; there was no tremor and no sensory change. No change in speech was noticed, but there was a silly facial expression. The pupils were entirely normal, as were the fundi, vision fields and cranial nerves. Mentally, the patient had recently begun to show some suspiciousness of his wife and children, his memory became impaired, and he showed a slight elevation, silly conduct, a happy, carefree expression and causeless laughter. He was decidedly more jovial and playful than when in his usual health, for his wife stated that he was ordinarily very quiet.

Case 6.—*History.*—A man, aged 33, married, and with one healthy child, had an entirely negative family history. He had never been sick, but had always been a very heavy drinker. Some years ago, the patient had worked in a manganese grinding plant but did not develop any symptoms at that time. After he was discharged from the army, he again worked for three months in a manganese grinding plant but had to stop on account of illness. He was so mentally abnormal at the time of discontinuing this occupation, and was drinking so heavily that he was committed to one of the state hospitals with the diagnosis of alcoholic psychosis. He was kept in this institution for two months and showed little improvement but was discharged.

He complained of stiffness and vague pains all over his body. The general physical examination was negative.

Neurologic Examination.—The patient showed a steady station; his posture was bent forward and his gait was slow and awkward; the deep and superficial reflexes were present and equal; there were no pyramidal tract signs, no cranial nerve involvement, no sensory changes and no incoordination. There was a marked anteroposterior head nodding, but no tremors of the extremities. There was a generalized muscular weakness without atrophy. The pupils were normal, the eye grounds showed a very reddened vascular retina with no changes in the disks. He had marked lack of expression with a more or less constant silly, causeless laughter. Mental examination showed the patient to be irritable and suspicious and at times, unruly and destructive. His speech was slow and monotonous, and he expressed himself very poorly. His memory was definitely impaired, and he was very asocial. Evidently there was present rather marked mental deterioration.

LABORATORY FINDINGS

It was not possible to obtain laboratory examinations in one of the six cases. A spinal fluid examination was made in each of the others. The cell count was above 10 in two: 12 and 14 cells per cubic millimeter. The globulin was normal, as were the pressures, colloidal gold curves and the Wassermann tests.

The blood Wassermann reaction was negative in all five cases. The spinal fluid and stools showed no trace of manganese in any case. The routine urine examinations were negative, but manganese was detected in the urine in three of the five specimens examined. In two of them, there was only a trace, but in one it was found in abundance, 5 mg. per liter. Manganese might have been found in each case had a larger quantity of urine been examined. In these examinations, 2 liters were used. The patient in whose urine manganese was found in the greatest quantity had discontinued work in the manganese dust two days before he was examined. The two patients in whose urine none of the element was found had been longest away from exposure. No examination of blood smears was made, but no changes in the size or shape of the red blood cells or material variation from normal of the white cells were found by a colleague who did make such a test in one of the cases here reported during the time the patient was most acutely ill.

It is generally agreed that manganese is eliminated chiefly in the feces and to a lesser extent in the urine. Wagner,[13] von Jaksch,[7] Seiffer[5] and all other investigators report no manganese in the urine of their clinical cases even though a careful search was made. In experimental studies on animals, Harnack[14] found only a minute amount of manganese in the urine and concluded that it was eliminated only in a small degree by the kidneys. Cahn[15] is also of the opinion, based on animal experimentation, that manganese is eliminated to some extent by the kidneys, but he found in no case the amount eliminated in this way proportionate to the amount introduced into the body.

COURSE AND PROGNOSIS

In persons who are susceptible to the invasion of the central nervous system by this poison, there appeared to be a gradual progression of the symptoms as long as they continued to absorb the manganese dust. The symptoms remained at the maximum for varying lengths of time and then tended to show gradual improvement up to a certain point. I am of the opinion, because of the well grounded belief that there is a destruction of cerebral tissue causing the symptoms of this condition, that there will be, except in the mildest cases, permanent disability of those poisoned by this metal.

PROPHYLAXIS

Prevention is a problem of the industrial hygienist rather than of the neurologist. Nevertheless, poisoning by the inhalation of manganese dust can certainly be prevented, provided very simple precautions are rigidly maintained. No face mask through which a man must breathe while at work is pleasant to wear, but, because of the dangers encountered, the wearing of an approved mask should be rigidly enforced. The exposed skin of men working in the mill which I inspected was literally caked with manganese; no gloves were worn, and the ore was thick under the nails. It is hardly conceivable that men working in this mill are very different from other mill workers, and, if this is true, we know that their personal hygiene is not all that could be desired. Therefore, the installation of showers, and insistence on the part of the mill operators that baths be taken and a change of working clothes be made at the end of each day's work is essential. A very important and necessary preventive measure would be an efficient fan-suction dust collector which would keep the air in circulation, collect a large part of the dust and thus lessen the chance of poisoning.

TREATMENT

The treatment suggested for the condition has been massage, corrective exercises, warm baths and various types of hydrotherapy, together with stimulation of the excretion of the poison by general elimination.

SUMMARY

1. Manganese, more often than is recognized, causes symptoms in workmen handling this ore.
2. That certain persons are not susceptible to the poisoning effects of manganese is demonstrated by the fact that many workmen in this plant have been in contact with manganese dust for several years with no apparent ill effect.
3. Mental symptoms have been described by some investigators and denied by others. Mental changes were found in each of the patients of this series.
4. No record could be found of other investigators having detected manganese in the urine in clinical cases. Experimentally, it had been found in minute amounts. In this series, it was present in three of the five specimens of urine examined.

212 West Franklin Street.

ARTHROPLASTY OF THE TEMPOROMAXILLARY JOINT *

FULTON RISDON, M.B.
TORONTO

To state briefly the anatomy of the temporomaxillary joint and its associated parts, first, from the osseous standpoint, there is the condyle and its neck, the sigmoid notch and the coronoid process. Overlying these structures, we have the zygomatic process and its anterior root, which is broad and strong, to terminate in a rounded eminence, the eminentia articularis. This eminence forms the anterior boundary of the glenoid fossa, and in the recent state is covered with cartilage. The middle root forms the posterior boundary of the mandibular portion of the glenoid fossa. The glenoid fossa is bounded posteriorly by the vaginal and auditory processes. The junction of the anterior root with the zygoma is a projection called the tubercle, for attachment of the external lateral ligament of the lower jaw. Between the anterior and middle roots is an oval depression forming part of the glenoid fossa for the reception of the condyle of the lower jaw. This fossa is bounded in front by the eminentia articularis; behind, by the tympanic plate and the auditory process, and is divided into two parts by a narrow slit, the gasserian fissure. The anterior or mandibular part, formed by the squamous portion of the bone, is smooth, covered in the recent state by cartilage, and articulates with the condyle of the lower jaw. This part of the glenoid fossa is separated from the auditory process by the postglenoid process, which, in mammalia, prevents backward displacement.

The ligaments that enter this joint are the external lateral, the capsular, and the interarticular fibrocartilage.

* Read before the Section on Stomatology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

Overlying this bony anatomy, the important structures that must be guarded are: of first importance, the frontal and orbital branches of the facial nerve, the temporal artery and its branch, the transverse facial, the temporal vein and the auricular temporal nerve. Immediately internal to the condyle is the internal maxillary artery, which is injured occasionally when the head of the condyle is removed. The temporal artery and vein, with its branches, occasionally gives a most troublesome hemorrhage when torn or cut unintentionally; but, generally speaking, the larger branches can be avoided. . It is the frontal and orbital branches of the facial nerve that are frequently severed in this operation, and, because of the uncertainty of their position, I suggest the vertical incision. I am sure that most operators have encountered the occasional case in which the frontal if not the orbital branches have been divided. This is not to be mistaken for the paresis shown in the inability to close the upper eyelid on that side following operation, which is due to the retraction during the operation. Here I would suggest that the mastoid self-containing retractor be used.

HISTORY

Briefly, the history is as follows: Humphrey reports resection of the head, in 1854; Grube, in 1863; Whitehead, in 1874, and König, in 1878. The operation has been modified by different surgeons. Helferich interposed muscle from the temporal; Mikulicz interposed masseter muscle, and Murphy used fascia from the temporal muscle. Roser interposed a gold plate; Payr suggested magnesium; Hofmann used free periosteum; Rochet and Poisson resected the ascending ramus. Many other operations have been suggested.

ETIOLOGY

The sexes are about equally affected. Orlow found sixty-eight patients (about 80 per cent.) between 1 and 10 years; 15 per cent. between 11 and 20; 5 per cent. between 21 and 30. Blair gives from 2 to 57 years, 25 per cent. of whom were under 10. In Orlow's cases, trauma was the cause in 29.4; otitis media, either primary or as a complication of some general infectious disease, 22 per cent.; osteomyelitis, periostitis of neighboring bones, 12.6 per cent.; rheumatic, gonorrheal and other inflammation of the mandibular joint, 10.5 per cent. Blair reports that 50 per cent. of his cases were due to trauma. In my series of seventeen cases, one was due to diphtheria, two were congenital and fourteen were due to trauma.

In considering this subject, I am following the classification of articular, extra-articular and articular-extra-articular. Three of my series were extra-articular and the others articular. I believe that a modified incision is much safer, and that in some cases of extra-articular trismus the epithelial inlay suggested by Esser in 1916, and modified by Waldron in 1917, at Sidcup, England, is most useful. I have searched the literature, and believe the method I am reporting is new, if not original.

OPERATION

The usual incision is L-shaped, the vertical limb extending from the level of the floor of the external auditory meatus and parallel with the ear but anterior to the temporal artery, and the horizontal or short limb extending forward slightly above the zygoma for about 2 cm., but only through the skin. I suggest that, because of the difficulty of locating with precision the orbital branch of the facial, which is frequently divided in this operation, only the vertical incision be made, about 1 inch long, starting from the level of the floor of the external auditory meatus. I fully recognize that this gives a poor exposure, but with patience, the condyle and even the coronoid may be removed through this incision. On removal of the condyle, I have filled the glenoid area with free fascia lata from the hip, and have also used Cargile membrane; but I prefer the former.

The value of any interposed tissue is open to doubt, as considerable experimental work has been done, more particularly with fat, which has disappeared in a very short time—in my own cases, within less than two months' time. I do believe that the holding apart of the remains of the ascending ramus and the cup-shaped cavity (the glenoid fossa) is important.

The shaping of the ascending ramus from which the head of the condyle has been removed is of great importance. It should be pointed anteroposteriorly and narrow laterally. By that, I mean that the new head should be diamond-shaped, and as narrow or thin as possible, in this way allowing for a very small attachment of fibrous tissue.

The case I wish to report in particular is one in which the trismus was due to a fibrotic change in the internal pterygoid muscle, due to shrapnel. The muscle was largely replaced by fibrous tissue, and the mouth could be forced open under a general anesthetic but would return to the fixed position in a short time. It was decided that an epithelization of that area would overcome the contraction due to the fibrous tissue. An epithelial inlay was implanted near the attachment of the internal pterygoid muscle through an incision parallel with the acclusal surface of the lower teeth. Dental compound was molded to fit in this incision, which had been carried well through the fibrous tissue and held in position by silkworm-gut sutures. It was necessary to implant three inlays before the mouth could be opened to its fullest extent.

The most satisfactory results we have obtained were in cases of extra-articular trismus due to the union of the coronoid process to the inner surface of the zygoma or to the base of the pterygoid process of the sphenoid. This was, of course, of traumatic origin. In these cases, the coronoid process was resected but the joint was left intact, and the result was excellent.

There is another feature of these cases that should not be neglected; that is, the recession of the chin. It has been suggested that a double resection of the ascending ramus be made and that the lower jaw be pulled well forward and held in this position by attachment to the upper jaw. This, I feel, is an excellent method if it can be used, but I have found it difficult to adapt this treatment for a number of my cases. I would suggest the following:

A seventh or eighth rib of the proper curvature and length should be taken from the patient and inserted over the mental process of the lower jaw. It is necessary in these cases to roughen the outer surface of the mandible and the inner surface of the graft, and wire it into position with any light wire, say the medium orthodontia wire. Needless to say, the technic of this operation is very exacting, as it is a free transplant, and in the dissection, one must not go too far up on the outer surface of the lower jaw, for fear of entering the mouth through the neck incision.

CONCLUSION

These cases, while they appear simple because the joint is superficial, present many difficulties, and the final results are not so uniform as one may desire; but in my short experience, by following the procedure outlined in this short paper, we were able to obtain even in the worst cases a moderately good result; consequently, I believe in the operation as near the joint as possible.

ABSTRACT OF DISCUSSION

Dr. T. E. Carmody, Denver: For a number of years I have used the incision Dr. Risdon recommends, and I can obtain plenty of opening through this incision for the removal of the condyle. As Dr. Risdon says, it is difficult at times because the opening is small, but by use of the mastoid retractor for forcing back the tissues, one can, as a rule, get sufficient opening for removal. The fact that paralysis does not develop or that one is not quite so liable to injure the temporal artery or the internal maxillary artery makes it worth while to take a little extra trouble. It prolongs the operation only a few minutes, but not enough to interfere with the tissue. For some years, I have not placed the tissue in between the parts of the mandible, and I find that my results are just as good, especially as there is such a small amount of tissue.

Dr. Robert Ivy, Philadelphia: I believe that Dr. Blair of St. Louis, in 1911, was the first one to advocate the interposition of temporal fascia, even before Dr. Murphy. The incision that Dr. Blair employs is most suitable when it is desired to use temporal fascia. The incision ascends vertically in front of the ear, then curves forward well above the zygoma. We do frequently get some paralysis of the occipital frontalis muscle, but I never have seen paralysis of the orbicularis palpebrarum.

Dr. Herbert A. Potts, Chicago: I should like to point out the dangers of wholesale extraction of teeth. The extraction of a tooth requires as much care, attention and thought as the opening of the abdomen, because of the complications that may follow. A young woman had three third molars extracted. Whether or not they were infected at the time or whether they became infected afterward I do not know, but, at any rate, she developed a pyremia, abscesses in each groin, a pleural abscess and an abscess in each parotid, from which she almost died. The parotid abscesses resulted in a complete bony ankylosis of both temporomandibular joints. The jaw was just plastered to the base of the skull from the joint clear out to the tip of the coronoid process. An incision was made similar to the one which Dr. Ivy showed, and the mandible was liberated from the base of the bone, but on one side, just after liberating the coronoid process, I opened a vein and a severe hemorrhage resulted. The wound was perfectly clean for a week, with only a provisional drain placed in it; a week later in operating on the other side, I made the mistake of opening the first wound and placing some fascia lata in at that time. On the left side one can hardly see the line of incision through which this operation was done. I think that, had I refrained from opening the first wound, I should not have had the slight infection and the scar on the other side. But the principal danger is in extracting a tooth, dismissing the patient, and not giving any further attention to him.

Dr. E. Fulton Risdon, Toronto: The interposition of material certainly is not necessary. I never take off the zygoma; it leaves things projecting in a rather unsightly way. If one takes off a section of the zygoma, of course, one must bring it over; it cannot be brought under. These operations should not be undertaken lightly; especially should the incision be kept high, never coming below the level of the floor of the external auditory meatus. A number of patients have come to me recently with a total paralysis of the muscles on that side: it is a question whether these anastomoses are very successful.

Gastro-Enterostomy.—Of all the operations for benign lesions of the stomach or duodenum, gastro-enterostomy has the widest range of usefulness. When indications are adequate, gastro-enterostomy leaves little to be desired.—Balfour.

THE TREATMENT AND PROGNOSIS IN MYXEDEMA [*]

CYRUS C. STURGIS, M.D.
AND
WALTER B. WHITING, M.D.
BOSTON

When Dr. George Murray [1] read his classic paper before the British Medical Association in July, 1891, on the treatment of myxedema by the administration of the thyroid gland of sheep, the medical world in general proclaimed, and quite correctly, that there had been discovered another specific remedy for what had usually been regarded as a hopeless condition. Marvelous as the cure may be in most instances, it is obvious to any one who has observed a group of these patients under treatment over a long period, that even though the diagnosis is correct and the preparation used in treatment is potent, there is often a failure, either partial or complete, to effect a cure. This may be due to several reasons which will be considered later, but undoubtedly the chief cause is the careless administration of a drug which must be given with the greatest exactness in order to produce satisfactory results. It is often apparent that mistakes in the management of these patients have been made because the treatment of myxedema has been considered too simple.

It is our purpose in this study to appraise carefully the method of treatment that has been used on a series of patients in this hospital in an endeavor to formulate a method whereby treatment can be administered with the greatest efficiency and safety. In addition, an opportunity has been afforded to observe a number of patients over a considerable period, and certain conclusions concerning the prognosis in this disease have been formulated.

This study is based on a series of twenty-six patients, all of whom presented the typical symptoms and signs of myxedema and, in addition, all had a characteristically diminished basal metabolism. A fairly large group of patients was excluded from the series as the diagnosis in some instances was in doubt or the condition atypical in various aspects. It is fortunate that the same preparation of dried thyroid gland (Armour's) has been used since the hospital was opened, and there has never been any conclusive clinical evidence that the potency of the drug has varied. There may be a great variation in the strength of the drug as prepared by different manufacturers according to the careful studies of Dr. Reid Hunt,[2] who has been interested in this important question for a good many years. In his opinion, this variation in potency results from the fact that there is no generally accepted standard for thyroid. At present, the most sensible procedure for the clinician is to use one preparation constantly and determine by careful clinical observations its strength and dosage. Treatment was controlled in all the patients of this series by (1) the clinical response of the patient, (2) the basal metabolism, (3) the resting pulse rate, and (4) the body weight. Data concerning this group of patients are shown in the accompanying table. No attempt will be made in the present paper to discuss the clinical aspects of myxedema or the relation of the low metabolism to the disease, as these features have been reported from the medical service of this hospital in a previous communication.[3]

METHOD OF ADMINISTERING THYROID GLAND

It has long been emphasized that the most satisfactory method of treating myxedema is to divide the therapy into two stages, (1) the initial dosage, which is calculated to restore the patient to a normal level of metabolism, and (2) the maintenance dosage, which is the smallest amount necessary to keep the metabolism within normal limits. For convenience, our experience in the management of each stage of the therapy will be considered separately.

In untreated patients with the characteristic picture of myxedema, we have found that the amount of dried thyroid gland which is necessary to restore the basal metabolism from the initial low point to normal has varied widely, as the total amounts necessary in this series have ranged from 2 3 to 6.5 gm. This variation has been due, in part at least, to the lack of a constant time interval over which the drug has been given. For example, in some patients the metabolism has been raised to normal by relatively large doses which were given for a few days, while in others the same result has been obtained by the administration of much smaller doses for a longer period. Future studies with a uniform dosage may yield more constant results. Several years ago, it was thought that it might be possible to estimate precisely the amount of dried thyroid necessary, from the patient's body weight and the degree of the change in the metabolism in a similar manner to the modern method of calculating digitalis dosage, in patients with heart disease, from the body weight. Our present experience has suggested, however, that sex, age, body weight, duration of the disease, severity of the symptoms, and the initial level of the metabolism bear no accurate or constant relationship to the amount of thyroid gland necessary to restore the patient to a normal condition.

Data in Thyroid Treatment of Twenty-Six Patients With Myxedema

	Age	Sex*	Initial Metabolism Before Treatment, per Cent of Normal	Duration of Symptoms	Maintenance Dose, Daily
1 G L F	22	♀	—34	2 yr	0 13 gm
2 I R F	22	♂	29	2 mo	0 13 gm
3 J F K	50	♂	—25	1 yr	0 13 gm
4 M H	50	♀	—28	6 yr	0 13 gm
5 M T M	73	♀	—33	28 yr	0 13 gm

While it may be possible to calculate the exact effect of a definite dose of thyroxin on a myxedematous patient when it is given intravenously, we have not been able to determine the effect of a known amount of dried gland with a similar degree of accuracy when given by mouth. This might be expected, however, as thyroxin is a highly refined preparation of known chemical composition, while "dried thyroid gland" is of a less definite nature and, moreover, can be given only by mouth. This, therefore, introduces the complicating factor that the drug may not undergo complete absorption in the gastro-intestinal tract. The failure to formulate a precise method of estimating the amount of dried thyroid gland to use in the initial stage has led to the adoption of a known safe dosage which is given over a variable length of time depending on its effect on the patient. In the average adult patient without complications, it has been found that a dosage of 0 13 gm (2 grains) three times a day can be continued with safety until the basal metabolism and pulse reach normal[4] With this dosage, the metabolic level and pulse rate usually reach normal in from five to ten days, although individual patients show a wide variation in this respect, and it is advisable, therefore, to keep the patient under close observation and continue with this amount until satisfactory results are obtained. In treating patients with uncomplicated myxedema, it is more satisfactory to confine them in a hospital for from two to three weeks, as this permits close observation and their activity can be controlled. As profound changes occur in the patient's metabolism during the early stages of treatment, it is desirable to keep them in bed for at least a week as a precaution against unpleasant symptoms.

If the patient is under observation in a hospital, the initial dosage of 0 13 gm. (2 grains) three times a day is continued until the metabolism and resting pulse rate approach normal and there is clinical evidence of improvement It has been our custom to determine the basal metabolism, resting pulse rate, and body weight at least every other day in order to control the dosage more accurately. After thyroid gland has been given in amounts of 0.13 gm. three times a day for three or four days, the first clinical evidence of a thyroid effect is shown by the patient experiencing a sensation of increased warmth, moderate sweating and accelerated mental reactions. Coincident with these changes, there is usually a slight increase in the resting pulse rate, averaging about 10 beats a minute, and, likewise, the basal metabolism shows an average rise of 10 per cent. At this time, the patient's temperature may become somewhat elevated above normal for a few days, the average, however, not exceeding 100 F. As untreated patients with myxedema frequently have a subnormal temperature, this change following treatment is one of considerable magnitude, and it is not uncommon for a patient under these circumstances to complain of malaise, mild generalized aches and pains, and loss of appetite. The drug should be continued, however, until the basal metabolism is between — 10 and — 5, according to the standards of Du Bois. While it is generally accepted that the normal varies between — 10 and + 10 according to these standards, it has been our experience that the average patient with myxedema more nearly approaches a condition approximating normal if the metabolism is maintained between — 5 and — 10. If the metabolism remains at this level for five or six weeks, there will be a loss of weight which averages from 10 to 15 pounds (4.5 to 6.8 kg.). This loss is due apparently to the disappearance of the subcutaneous, nonpitting edema that is characteristic of the disease. After several months of treatment, it is commonly observed that the patients regain this weight and 5 or 10 pounds (2.3 or 4.5 kg.) in addition, which doubtless results from their greatly improved general nutrition.

[4] The same amount may be given four times a day if the patient is under observation in a hospital and no complications exist

After the patient's basal metabolism and pulse rate have been restored to normal and there has been evidence of clinical improvement, the second stage of treatment is begun. The object at this time is to determine the exact dosage which will maintain the metabolism at the proper level. This has been called the maintenance dose, and is the amount that is to be taken by the patient each day. This dosage when once established is usually constant and in most instances must be continued throughout a patient's life, although occasionally the size of the dose must be altered, and in very rare instances it appears that there may be complete recovery from myxedema, as the drug may be discontinued without a recurrence of the disease. Our experience has taught us that most frequently the correct dose is in the vicinity of 0.13 gm. (2 grains) a day, although in individual patients the amount has varied from 0.065 gm. (1 grain) to 0.195 gm. (3 grains) daily. In a study of twenty-five patients with myxedema who have been observed over a sufficient length of time to make our results significant, we found that fourteen required a maintenance dose of 0.13 gm. (2 grains) daily; six, a dose of 0.195 gm. (3 grains); two, a dose of 0.065 gm. (1 grain), and three, a dose of 0.098 gm. (1.5 grains). Occasionally a patient has taken as much as 0.39 gm. (6 grains) as a maintenance dose for a short period, but this amount has invariably produced symptoms of overdosage if continued for any length of time.

It is possible to carry out the entire treatment in the patient's home, although the results are less satisfactory, as the dosage cannot be regulated with great accuracy. Moreover, a longer time is required to restore the patient to normal, as the initial dosage must be smaller in order to avoid the possibility of undesirable symptoms. After the diagnosis has been established, if it is desired to treat the patient at home, the following plan has been found to be satisfactory: Dried thyroid gland is given in a dosage of 0.13 gm. (2 grains) three times a day for five days. During this interval, the patient should be confined to the house and should spend a major part of the time resting in bed. Each day the pulse rate should be counted by the patient or by some member of the family, before the patient arises in the morning. In this way the basal pulse rate is obtained, and such factors as food and muscular activity, which influence the pulse rate, are eliminated. In the absence of basal metabolism estimations, a careful determination of the resting pulse rate is of great value as it gives an accurate idea of the basal metabolism in most instances. This relationship has been emphasized in a previous communication[5] from this hospital and has been confirmed by others.[6] Under certain conditions, however, such as complete heart block, the pulse rate may remain unchanged despite an increase in the basal metabolism.

Such an occurrence is illustrated by the case record of a patient reported by Aub and Stern.[7] A young woman with a complete heart block and a pulse rate which varied from 49 to 63 a minute was given large doses of thyroid substance. Although the basal metabolism increased to + 40, there was no coincident changes in the pulse rate. Such a possibility, although rare, should always be considered if the pulse rate is used as a guide to the administration of thyroid gland. The body weight should also be obtained before the treatment and again at the end of five days. If the resting pulse rate has not increased above 80 a minute and there has been a loss of only 2 or 3 pounds (0.9 or 1.4 kg.) in body weight, there is no indication of overdosage, provided the patient does not complain of palpitation, dyspnea, excessive warmth, dizziness or nausea. If all is satisfactory, the treatment may be continued by giving the thyroid tablets in amounts of 0.13 gm. twice a day. This dosage should be maintained until the resting pulse rate is in the vicinity of 75 a minute, unless symptoms of overdosage appear. When the pulse rate reaches a satisfactory level, the amount of thyroid gland that is given should be reduced to 0.13 gm. daily, and this should be considered as the maintenance dose. A determination of the basal metabolism at weekly intervals is very helpful in regulating the treatment.

The chief difficulties that are encountered in the management of patients with myxedema may for the most part be attributed to careless observation on the part of the physician or failure of the patient to follow instructions. If a patient with myxedema is given a prescription for thyroid tablets and instructed to take a certain number each day and report back in a few weeks, the possibility of an underdosage or overdosage is likely. The latter more commonly occurs with the result that unpleasant and possibly serious symptoms develop. This is unfortunate as the patient is frequently reluctant to continue with further treatment, since in most instances following an overdosage there develops an abnormal fear of the drug, and a tendency to attribute every possible symptom that develops thereafter to an excess of the thyroid substance.

An additional difficulty in the treatment of myxedema is the lack of cooperation of the patient. This is shown by the observation that approximately one fourth of our patients have at some time during the course of their treatment discontinued taking thyroid tablets of their own volition, despite our instructions. As a result they have had, with a very rare exception, either a partial or a complete relapse of the disease. This lack of cooperation results from a failure of the patients to appreciate the importance of continuing with the drug after all symptoms of the disease have disappeared. After the drug has been omitted for a period of several weeks, the condition of partial or complete myxedema again becomes apparent, with a rare exception. Following this, the characteristic mental dulness and lack of interest become manifest, and the patient no longer has the initiative to consult a physician. On account of the tendency of so many to discontinue treatment, we have for the last three years required all patients with myxedema to report to the outdoor department at regular intervals for observation, in order to eliminate this important cause of therapeutic failure. At each visit a careful examination is made, and if there is any indication that the optimal treatment is not being carried out, the basal metabolism is determined and the dosage is adjusted accordingly. If it becomes necessary to adjust the maintenance dosage, the patients are required to record their resting pulse and body weight daily over a period of several weeks. These data, when considered with a careful inquiry into the symptoms and combined with the basal metabolism determinations, eliminate careless observation and afford an accurate guide for the proper regulation of treatment.

SERIOUS COMPLICATIONS THAT MAY BE ENCOUNTERED IN TREATING PATIENTS WITH MYXEDEMA WITH THYROID GLAND

There are several complications that may exist in patients with myxedema which make the administration of thyroid gland a somewhat hazardous procedure unless the treatment is very carefully controlled. The complications involve chiefly the heart, kidneys and blood and are observed more frequently in the middle aged or elderly patients

Recently, Fahr[8] has emphasized that in myxedema there may be definite symptoms and signs of heart failure which do not respond to the therapy of rest and digitalis but are cured by thyroid medication. Fishberg[9] has likewise pointed out that a greatly dilated heart occurs commonly in myxedema and, furthermore, a generalized arteriosclerosis may be observed even in young patients. The latter reported the case of a man, aged 21, with myxedema, in whom necropsy showed an enlarged heart and, in addition, a generalized arteriosclerosis, which included atheromatous patches of the arches of the aorta, was present. Swan[10] has reported his observations on a patient with myxedema in whom auricular fibrillation appeared following the use of thyroid substance. The rate became regular when the drug was discontinued; auricular fibrillation reappeared on renewal of the treatment and disappeared a second time when the drug was withdrawn. The point we wish to emphasize is that patients with myxedema may have a serious impairment of the myocardium, and this may be improved or cured by the administration of thyroid gland; but under these circumstances, the drug should be given with great caution as otherwise unfavorable and fatal results may follow. This is well illustrated by the following case report of a patient who was recently observed in the Peter Bent Brigham Hospital:

M. H. B., a Scotch woman, married, aged 50, entered the hospital, Feb. 17, 1925. She gave the classic history of myxedema extending over a period of several years, and this was confirmed by the physical examination and a basal metabolism of —32. In addition, the patient gave a history of angina pectoris and, furthermore, showed a severe anemia as indicated by a red blood count of 2,000,000 cells per cubic millimeter. Treatment was given in the form of dried thyroid gland in doses of 0.13 gm. (2 grams) three times a day. After six doses were taken, the temperature suddenly rose to 101 F. but returned to normal in a few hours. There was no apparent explanation of the febrile reaction, and as there was no other evidence at the time that the dosage was excessive, it was decided to continue with the thyroid therapy. Accordingly, eight more doses of 0.13 gm. were given in the next twenty-four hours. The basal metabolic rate at this time was found to be —11. The patient's condition, however, suddenly became alarming, as indicated by a weak, feeble pulse of 120 a minute, cyanosis, cold and clammy skin, and a temperature of 101 by mouth. Although the thyroid medication was immediately discontinued, it was a week before the patient recovered from this state of profound collapse. Following this, the thyroid substance was omitted for sixteen days, and during this interval digitalis was administered in full doses. At the end of this time, dried thyroid gland was again given in doses of 0.03 gm. twice a day. Two days later, the patient was found in collapse and pulseless and died in a few minutes without regaining consciousness. Necropsy showed coronary arteriosclerosis, cardiac infarction, hypertrophy and dilatation of the heart, atrophy and fibrosis of the thyroid gland and generalized arteriosclerosis.

This fatality illustrates very strikingly the disaster that may follow the administration of thyroid gland in a patient who has serious heart disease. Apparently the myocardium of this patient was unable to meet the strain imposed on it by the increased cellular metabolism that followed the use of thyroid gland, even in moderate doses. Under the circumstances, there was an increased demand for oxygen by the body tissues, and this could be delivered to the cells only by the blood stream. As a result, it was necessary to augment the circulation rate, and an added strain was thereby put on the heart muscle, which was unable to respond. An added handicap was the frequently observed anemia of the disease[11] as indicated by a red blood count of 2,000,000 cells per cubic millimeter, which resulted in a diminished ability of the blood to carry oxygen. Consequently, the heart was obliged to perform much more work, as each unit of blood carried less oxygen than normal and, therefore, a greatly increased circulation rate was necessary. This experience taught us that a more logical and safer procedure to carry out in such a patient is to give two or three blood transfusions of from 250 to 300 c.c. each and thereby increase the oxygen carrying capacity of the blood. Moreover, such a patient should be thoroughly digitalized. It is also of great importance that the initial doses of thyroid gland should be exceedingly small, such as 0.03 gm. (one-half grain) twice a day. If no untoward symptoms develop, the dose may be cautiously increased.

In addition to changes in the heart and blood, it has long been known that a majority of patients with myxedema have albumin and casts in the urine, and some have a definite renal insufficiency, as shown by the functional tests. The danger that may result under these circumstances is well shown by the studies of Bowen and Boothby[12] which were reported from this hospital in 1917. They found that moderate amounts of thyroid gland by mouth, in patients with chronic nephritis, caused an increase in the blood urea nitrogen and serious effects may result. In one case that they reported, the blood urea nitrogen rose, during the course of a few weeks, from 148 mg. per hundred cubic centimeters of blood to 216 mg. following thyroid feeding. From these studies, it is obvious that all patients with myxedema who are unable to excrete nitrogen in normal amounts, as indicated by an accumulation of nitrogenous products in the blood stream, should be given thyroid gland medication with extreme caution.

It seems advisable, therefore, before giving thyroid gland by mouth to a patient with myxedema, to consider carefully the patient's history, physical examination and laboratory studies, and to ascertain whether there are any abnormalities of the heart, blood or kidneys. If complications are present, the patient should be kept strictly in bed and thyroid given in very small amounts. If the heart is markedly involved, digitalis and rest should be given before treatment with thyroid gland. If the patient has an anemia, a transfusion should be considered before the thyroid treatment is begun. If a chronic nephritis exists and there is impaired renal function, the thyroid dosage should be small, the diet reduced in protein, and constant watch should be kept of the blood urea nitrogen.

THE PROGNOSIS IN MYXEDEMA

It is commonly accepted that a patient who is suffering from myxedema can be restored to normal health by the proper administration of dried thyroid gland. It is likewise thought that it is necessary for a patient with myxedema to continue taking thyroid gland substance indefinitely, in order to remain in normal health. While these statements are essentially true, both have had what appeared to be exceptions, in our experience.

The prognosis for cure should also be guarded if the patient shows advanced lesions involving the central nervous system, heart or kidneys. While the general condition may be markedly benefited and the complicating factor may likewise show improvement, it is too much to expect that definite anatomic changes in the heart, nervous system or kidneys can always be completely eradicated. The following record indicates the wisdom of a guarded prognosis in a patient with myxedema and an advanced renal lesion.

A woman, aged 62, had had the characteristic symptoms of myxedema for ten years. Physical examination showed the striking signs of the condition, and, in addition, there was evidence of renal injury as indicated by albumin and casts, and a phenolsulphonephthalein excretion of 8 per cent. in two hours and ten minutes. Following the careful administration of thyroid gland, there was a complete disappearance of all symptoms that could be attributed to the lack of thyroid secretion. In addition, the renal lesion showed some improvement, but the patient died in a few months of uremia.

Serious mental changes are likewise difficult to effect although the general symptoms and signs of myxedema in such a patient may be relieved. The following case record illustrates the inability of thyroid medication to relieve mental symptoms in this condition:

An Irish domestic, unmarried, aged 50, entered the hospital, Dec. 30, 1923, complaining of a gradually increasing loss of strength and energy of six years' duration. The patient had observed dryness of the skin, loss of hair, absence of sweating, and susceptibility to cold for several years. Her memory had failed a great deal, and there had been a very evident mental retardation. The basal metabolism was —28, and the resting pulse rate 54 a minute. Following careful treatment with thyroid gland, the basal metabolism and pulse rate returned to normal, and the general symptoms of myxedema disappeared. After the patient had remained on a maintenance dose of 0.13 gm. a day for several months, she discontinued the thyroid tablets on her own responsibility. Six weeks later, the metabolism was found to be within the limits of normal despite the lack of thyroid medication. Moreover, there was no evidence of a recurrence of the indications of myxedema, such as dry skin, loss of hair, or susceptibility to cold. The mental condition was progressive, and in a short time the deterioration became so marked that it became necessary to admit her to a hospital for treatment of mental disorders. The last basal metabolism, which was normal, was determined after she had not taken thyroid gland for four or five months.

This case illustrates two points of importance in the treatment of myxedema: (1) Serious mental changes which may be associated with the disease are not always relieved by thyroid therapy, and (2) in some instances the metabolism may remain within normal limits for at least four or five months after the thyroid medication is discontinued.

Further evidence that a patient may recover from spontaneous myxedema is furnished by the history of the following patient:

A grocery clerk, married, aged 33, who entered the hospital, Dec. 29, 1916, was found to have a dry, scaly skin, slow speech, retarded mental reactions, and loss of hair. The patient's temperature was subnormal, the resting pulse rate was 71 a minute, and the basal metabolism was —26. Thyroid therapy was instituted and was followed by a striking improvement in the patient's condition. The skin became warm and moist, a regrowth of hair occurred, and the appetite increased. He became more active physically and mentally. Six months later the thyroid tablets were discontinued because the patient felt so well. He was not seen again until October, 1924, eight years later, at which time he appeared at the hospital merely to report how well he had been. During this interval, all medication had been stopped, and the patient had remained in perfect health. The basal metabolism in October, 1924, was found to be +11.

Such evidence that a patient may make a recovery must be accepted with caution and should only be regarded as suggestive, as it is difficult to prove conclusively that the patient was suffering from myxedema when first observed in 1916, although the evidence in favor of this diagnosis is very strong. While these two exceptions have been observed, it can be stated definitely, however, that in almost every instance there is very little tendency toward spontaneous recovery, and that continued therapy throughout a patient's life is necessary for the maintenance of normal health.

DANGERS IN THE USE OF CERTAIN HALOGENATED PHTHALEINS AS FUNCTIONAL TESTS *

W. H. ROSENAU, M.D.
BANNING, CALIF.

In the last few years, certain halogenated phthalein compounds have come into widespread use as test materials for hepatic function and as mediums for cholecystography. For some time I have been using several of these compounds and have noticed, as a result of the intravenous injection of them into patients, reactions that are, potentially at least, dangerous to the individuals so treated. It is somewhat surprising that, in spite of the rather voluminous literature dealing with these substances, so far little attention has been paid to the untoward reactions following their use. The most important of these compounds has been phenoltetrachlorphthalein, but recently tetrabromphenolphthalein and tetra-iodophenolphthalein have become quite prominent in cholecystography.

Rowntree, Hurwitz and Bloomfield[1] were the first to make clinical use of phenoltetrachlorphthlein as a liver function test. Because of the many difficulties inherent in the measurement of the amount of dye recovered in the feces, it was not long before McNeil[2] utilized the collection of the duodenal contents to deter-

mine the appearance time of the dye in this fluid. Not until 1922, when Rosenthal[3] offered his modification, did the test receive any widespread use. His procedure was to inject the dye intravenously, in a dosage of 5 mg. per kilogram of body weight, and then to examine the rate of disappearance of the dye from the blood stream. Because of the difficulty often encountered in securing sharp or accurate readings, when there was present lipemia, bilirubinemia or hemolysis in the serum, Bloom and Rosenau[4] increased the accuracy of the test through acetone precipitation of the serum to be tested. Maurer and Gatewood,[5] utilizing the principle of acetone precipitation, have recently published an account of a method by which blood can be drawn from the ear by means of a blood-counting pipet, for the determination of the dye content of the serum.

Since Rosenthal presented his method, a large literature on the subject has made its appearance. Other than the developments of technic noted above, the great mass of the reports have been restricted to an evaluation of the method in the light of clinical results. The untoward reactions obtained following the use of phenoltetrachlorphthalein have been insufficiently emphasized.

UNTOWARD REACTIONS

1. *Thromboses.*—Rowntree, Hurwitz and Bloomfield, in their early work, stated that the alkali salts of phenoltetrachlorphthalein, administered subcutaneously, act as decided irritants unless they are highly diluted, as "such salts formed, as they are, by neutralizing a very weak acid with a very strong base are strongly hydrolized in aqueous solution and hence act on the tissues like solutions of caustic soda." In their clinical investigations they gave 8 c.c. of the dye, 400 mg., intravenously by the gravity method and washed through by from 50 to 100 c.c. of distilled water. Of the sixty-seven cases reported, in which this method was used, ten thromboses were encountered (over 13 per cent.). They stated that thromboses occur only when there is "marked anemia, myocardial insufficiency or advanced phlebosclerosis." Sisson,[6] using 8 c.c. of the disodium salt diluted in 100 c.c. of physiologic sodium chlorid solution, reported five thromboses in thirty-nine patients (13 per cent.). He stated that the thromboses had no relation to the disease of the patient. Chesney, Marshall and Rowntree[7] reported eight thromboses in a series of 113 cases (7 per cent.). They emphasized that thromboses frequently follow at the point of injection, as evidenced by a slight local pain or tenderness or a sense of resistance offered the palpating finger. McNeil,[2] Kahn,[8] Aaron, Beck and Schneider,[9] Williams[10] and others failed to mention the presence or absence of thromboses in their studies.

Rosenthal in his early communications gave no statistics regarding the frequency of thromboses, but advised an adequate dilution of the drug in physiologic sodium chlorid solution, as he stated that the undiluted dye might cause local irritation and occasionally thrombosis. Friedenwald and Gantt,[11] in a report covering 169 injections, commented on "several instances of thrombosis from the action of the concentrated dye on the walls of the vein at the site of injection." They reported that they had not noted a single untoward reaction, since they had been using sterile physiologic sodium chlorid solution as a diluent. In a few other communications, passing mention of the occurrence of thromboses is made.

More recently, Bloom and Rosenau[4] reported four thromboses in twenty-seven cases (14.8 per cent.). In this series, I took every precaution to prevent the occurrence of either a local reaction or a thrombosis. The dye was diluted 1 part to 2, 3 or 4 parts of sterile physiologic sodium chlorid solution and, following the injection, from 10 to 20 c.c. of physiologic sodium chlorid solution was injected, in an attempt to wash away any of the dye that might be adherent to the vein wall at the site of injection. Care was also taken to prevent any leakage of the dye into the subcutaneous tissues. These added precautions, in addition to gentle handling of the tissues, did not prevent the occurrence of local tissue reactions or thromboses. In one of the cases of thrombosis in our series, a thrombus formed in the vein from which the blood was withdrawn, as well as in the vein into which the injection of the dye had been made. The thromboses appeared from twenty-four to forty-eight hours following the injection and had the usual characteristics. Maurer and Gatewood suggest that the thromboses are perhaps due to the throwing down of the dye in colloid suspension in the blood, and the presence of the dye in this colloid form in the blood stream produces the thromboses. Rosenthal and White,[12] in their recent report advocating the use of the disodium phenoltetrabromphthaleinsulphonate test for hepatic function, state that "irritation of the vein wall is frequent, and occasionally systemic reactions occur in the use of phenoltetrachlorphthalein."

2. *Local Reactions Occurring at the Site of Injection.*—Attention has not infrequently been called to local inflammatory reactions expressed by induration, infiltration, redness, tenderness and pain at the site of injection of phenoltetrachlorphthalein. Abel and Rowntree[13] and other early workers noted the irritating action of the disodium salt, when injected subcutaneously. Rosenthal diluted the dye in physiologic sodium chlorid solution and washed the vein with the same fluid after injection, in order to avoid the local irritating action of the dye. Friedenwald and Gantt held a piece of gauze firmly around the needle when it was being withdrawn, in order to prevent any return leakage. Bloom and Rosenau reported six local reactions in twenty-seven cases (22 per cent.).

3. *Chills.*—The earliest cases of chills reported were possibly due to the use of distilled water as a diluent for the dye instead of physiologic sodium chlorid solu-

tion. Sisson[6] reported a rise of temperature as high as 101 F. in one case in his series. The occasional occurrence of chills following the injection of the dye was noted by other earlier workers. In our series two chills were encountered in twenty-seven cases (7.24 per cent.). In one case the temperature rose as high as 102 F. by mouth. The chills occurred from twenty to thirty minutes after the injection. Maurer and Gatewood also reported the occurrence of chills with a rise in body temperature. They reported one case in which the temperature rose to 105 F. forty minutes following the injection. It is probable that chills have been encountered by other workers but not mentioned.

In our work we encountered ten untoward reactions (thromboses, local reactions and chills) in twenty-seven cases (37 per cent.) subjected to the phenoltetrachlorphthalein test. Because of these reactions, the number of clinical injections in the series we reported was curtailed.

4. *Deaths.*—Rowntree, Hurwitz and Bloomfield[1] reported one case of unexplained death, occurring six days after the injection of the dye. Maurer and Gatewood recently reported three patients in their series who died from two to seven days after the test was made. Two of the three cases showed recent thromboses, the dye being qualitatively demonstrated in one thrombus. These deaths may possibly have been caused by the production of fatal thromboses as a result of the injection of the dye.

5. *Other Symptoms.*—1. A sensation of dryness is a common occurrence from ten to fifteen minutes after the injection. The patients put out their tongues, lick their lips and complain of dryness of the mouth.

2. Pain over the liver region was complained of occasionally.

3. Purgative action lasting six days was reported by early workers. In our clinical series, little, if any, laxative effect was noted.

CLINICAL AND EXPERIMENTAL WORK INDICATING STRAIN ON OR DAMAGE TO THE LIVER

Early workers reported that the dye could be repeatedly injected in large quantities, over a period of many months, without any demonstrable ill effects to the animal. Bloom and Rosenau,[4] in experimental and clinical studies, called attention to a constant increase in the bilirubin content of the blood, following the injection of the disodium salt of phenoltetrachlorphthalein. Normal as well as abnormal cases showed uniformly a definite increase in the indirect van den Bergh test. When the van den Bergh test was positive by the indirect method alone, or by the direct and indirect, before the injection of the dye, there was always a uniform increase in the intensity of the van den Bergh reaction, in the direct and indirect, after the injection. The increase in the van den Bergh reaction was found at the end of one hour following the injection, and disappeared within twenty-four hours. This temporary hyperbilirubinemia seemed to bear no relation to the severity of the impairment of the liver function, as measured by the dye retention. Interpreting this hyperbilirubinemia, it was stated: "We believe that the transient bilirubinemia subsequent to the injection of phenoltetrachlorphthalein was due to the fact that the liver, having an apparently specific, excretory action toward the dye after it has been injected intravenously, cannot excrete bilirubin or its precursors which are brought to it until all of the dye has been eliminated. We have no evidence that this transient bilirubinemia is indicative of anything more than a temporary functional blockade of the bilirubin excreting power of the liver."

Because of this hyperbilirubinemia occurring constantly following the injection of the dye at that time, we felt that one should be cautious in injecting the dye in cases in which there had been a great amount of liver damage or injury. It was felt that in cases of severe liver damage, such as acute yellow atrophy of the liver, chloroform poisoning or severe cirrhosis, the injection of the dye might possibly add such a burden to the liver, in the attempt at removal from the blood stream, as to result in the subsequent death of the patient, as a result of hepatic insufficiency. A good parallel is the addition of a small strain to a badly damaged heart muscle, with a very small amount of reserve, with the death of the patient.

Recently Ottenberg and Abramson[14] have reported the production of liver necrosis in rabbits following the injection of a 5 per cent. solution of either phenoltetrachlorphthalein or tetrabromphenolphthalein in doses of 0.3 to 0.4 gm. per kilogram of body weight. Larger doses killed the rabbits at once or within fifteen minutes, with "acute convulsive symptoms." They call attention to the fact that the doses needed to produce severe symptoms and liver lesions were enormously larger than those used in the phenoltetrachlorphthalein liver function test (0.005 gm. per kilogram being equal to the clinical dosage). These observations give added significance to the observations of the occurrence of a hyperbilirubinemia, following the injection of phenoltetrachlorphthalein.

ATTEMPTS TO MAKE PHENOLTETRACHLORPHTHALEIN NONIRRITATING ON INJECTION

Phenolsulphonephthalein injected subcutaneously, intramuscularly or intravenously is followed by no local reactions or thromboses. Phenolphthalein also is nonirritating. These facts suggested that the chlorin radical might be responsible for the irritating nature of the dye. Attempts were made to neutralize a possible theoretical liberation of chlorin in the tissues, or to modify the hydrogen ion concentration of the injected dye.

The disodium salt of phenoltetrachlorphthalein was diluted in the following sterile solutions:

1. Distilled water.
2. Physiologic sodium chlorid solution.
3. Sodium bicarbonate, 5 per cent. solution.
4. Sodium carbonate, 5 per cent. solution.
5. A phosphate buffer solution.

A phosphate buffer solution, when added to the dye, decolorized it and also resulted in the formation of a white precipitate. Because of this, the buffer solution was not used in the following experiments.

Rabbits' ears were used for the injection of the dye diluted in the various solutions to determine whether or not the character of the solvent might modify the irritating nature of the dye. The dye was made up in various dilution strengths and then injected superficially in the rabbit's ear. Injection was stopped when a small wheal had been produced. A control injection of the diluent was also made. The results obtained are given in Table 1, the percentage strengths being the actual dye contents of the solutions.

From the table it can be seen that the disodium salt of phenoltetrachlorphthalein, dissolved in water, 5 per cent. sodium bicarbonate, 5 per cent. sodium carbonate, or physiologic sodium chlorid solution is irritating and capable of producing inflammation on injection in the rabbit's ear, even in dilutions as low as 0.15 per cent. If one applies these results to the carrying out of the test on human beings, one would perhaps be justified in assuming that the disodium salt of phenoltetrachlorphthalein, even when diluted 1 part of dye to 30 parts of physiologic sodium chlorid solution, will possibly still be capable of producing irritation and inflammation at the site of injection. In the clinical test, a man weighing 70 kg. (150 pounds) is given 7.5 c.c. of the dye (1 c.c. containing 50 mg.). To inject 7.5 c.c. of the dye, it would be necessary to use over 200 c.c. of a diluent, to make up the 0.15 per cent. solution. The impracticability of such a procedure obviously eliminates this method from clinical use.

---

[14] Ottenberg, Reuben; and Abramson, H. A.: Production of Liver Necrosis by Tetrachlorphenolphthalein and Tetrabromphenolphthalein, J. A. M. A. 84:800 (March 14) 1925.

The untoward results described above have not been confined to the use of phenoltetrachlorphthalein. The *introduction of tetrabromphenolphthalein for cholecystography* has been followed by severe reaction on the part of some of the patients subjected to this test. In my own early experience with this substance, its intravenous injection into a middle aged man, for the purpose of obtaining a gallbladder shadow as a diagnostic aid, was followed within a few minutes by collapse, with a very feeble, rapid pulse. He recovered after hospitalization, but his condition following the injection was alarming.[15]

Whitaker and Milliken,[16] who used tetrabromphenolphthalein in only from 1 to 2 per cent. solution in physiologic sodium chlorid solution, asserted that they had only one reaction with headache, chills and vomiting in a series of twenty cases. Graham, Cole and Copher [17] have recently reported that a 12.5 per cent. solution of sodium tetra-iodophenolphthalein, which they use in cholecystography, at times produced induration at the site of injection. Thromboses following the injection of tetrabromphenolphthalein have also been reported by Smithies and Oleson.[18] Because of the toxicity of these substances following inravenous injection,[19] Menees and Robinson [20] have successfully administered tetrabromphenolphthalein by mouth, in capsules treated with formaldehyd to render them insoluble in the stomach, and Stewart [21] has obtained satisfactory results by the administration of tetra-iodophenolphthalein into the jejunum through a duodenal tube.[22] It has been concluded that "in spite of the toxic properties of the drug no fatal results due to its administration have been reported, but there is no doubt that much harm and even fatalities might be caused by overdosage." [19]

TABLE 1.—*Reaction Observed in the Ears of Rabbits Twenty-four Hours After Injection of Phenoltetrachlorphthalein Dissolved in Various Solutions*

Diluents	Diluent Unchanged 5%*	2 5% Sol. Dye	1 2% Sol Dye	0 6% Sol. Dye	0 3% Sol Dye	0 15% Sol Dye
Distilled water.....	No reaction	Necrotic ulcer	Slight ulceration	Well marked infiltration	Infiltration	Slight infiltration
5% sodium bicarbonate	No reaction	Necrotic ulcer	Slight ulceration	Well marked infiltration	Infiltration	Slight infiltration
5% sodium carbonate	No reaction	Necrotic ulcer	Slight ulceration	Well marked infiltration	Infiltration	Slight infiltration
Physiologic sodium chlorid solution	No reaction	Necrotic ulcer	Slight ulceration	Well marked infiltration	Infiltration	Slight infiltration

* Five per cent. solution of disodium salt of phenoltetrachlorphthalein contained in ampules put out by Hynson, Wescott and Dunning

It would therefore appear that the bromin and iodin phthalein compounds used in cholecystography possess to greater or lesser degree the irritating and toxic properties of phenoltetrachlorphthalein. I cannot help but advise against the indiscriminate injection of these halogenated phthaleins, especially because I feel that additional chemical research and further animal experimentation will probably result in the introduction of *compounds that are as innocuous as phenolsulphonephthalein* has proved to be and as Rosenthal and White [12] claim disodium phenoltetrabromphthaleinsulphonate to be. They recommend the use of disodium phenoltetrabromphthaleinsulphonate as superior to phenoltetrachlorphthalein for liver function work, in that it is a more delicate test and is nonirritating. In fifty tests, on human beings, no untoward effects of any kind were experienced.

SUMMARY

Following the use of phenoltetrachlorphthalein, thromboses, local inflammatory reactions at the site of injection and chills have been encountered by many observers. Several deaths probably due to its use have been reported.

Clinical and experimental work indicates the possibility of strain or damage to the liver, following injection of the dye.

Attempts to make phenoltetrachlorphthalein nonirritating on injection have failed.

Many observers have noticed severe toxic reactions following the use of tetrabromphenolphthalein and tetra-iodophenolpththalein.

The toxicity of the halogenated phthalein compounds should lead to caution in their use. Indiscriminate administration and overdosage should be avoided.

Insanity and Marriage.—When there is evidence of insanity or epilepsy in both stocks, or a general neuropathic tendency indicative of mental instability, the liability to dementia praecox is greatly increased in the descendants; therefore in advising (as one often has to do) in regard to marriage, evidence pointing to these special forms of mental disease in both stocks, on one side, still more on both sides even if shown in collaterals, induces one to say definitely from a eugenic point of view that it would be inadvisable—inasmuch as the risk of an insane inheritance for the children is so much the greater—Mott, Frederick: The Harveian Oration on Some Developments of Harvey's Doctrine, "Omne vivum ex ovo," *Lancet*, Oct. 24, 1925.

THE GALLBLADDER AS REVEALED BY THE ROENTGEN RAY

SIDNEY LANGE, M.D.
Professor of Radiology, University of Cincinnati College of Medicine
CINCINNATI

More than twenty years ago when Rieder gave the first bismuth meal, it was observed that the stomach was not located horizontally in the epigastrium, but that, in the average person, it hung vertically on the left side of the abdomen, its lower pole reaching to the level of the navel and usually below the navel. This observation was not immediately accepted by clinicians, because it did not seem to agree with the observations made, over a long period of years, by surgeons doing abdominal operations and by pathologists while making necropsies. The unique value and accuracy of roentgen-ray stomach visualization is now universally accepted, however.

The visualization of the gallbladder by the use of the tetra-iodophenolphthalein test, as brought out by Graham and his co-workers, promises to be an equally important milestone for clinical medicine. The oral administration now permits of universal application of this test without danger or discomfort to the patient.

During the last four months we have used the tetra-iodophenolphthalein test by the oral method to visualize the gallbladder in 500 routine abdominal roentgen-ray examinations. By perfecting the technic, we have been able to obtain, in the last 200 cases, a distinct gallbladder outline in more than 90 per cent. of the normal cases. A comparative study of the films obtained in this series shows that the normal gallbladder varies so greatly in location that we are impelled to ask: "Where is the normal gallbladder?" In answer thereto, we feel justified in saying that in the great majority of persons the gallbladder is not in the gallbladder region as clinically understood. This rather bizarre statement will demand some further explanation and discussion.

The gallbladder region, as given in Morris' Anatomy, is the right hypochondrium and epigastrium. The longitudinal line that separates the right hypochondrium from the epigastrium is said to cut the gallbladder. The lower limit of the right hypochondrium and epigastrium is the line connecting the tenth costal cartilages, and this line bisects the body of the second lumbar vertebra.

In my series of cases, the gallbladder extends either partly or wholly below the lower limits of the hypochondriac and epigastric regions in 75 per cent. of the cases. Usually it descends into the umbilical region but quite frequently into the right lumbar region.

Furthermore, in the 25 per cent. of the cases in which the gallbladder is found above the second lumbar vertebra, that is, in the so-called gallbladder region, it does not always lie in the line that separates the hypochondrium and epigrastrium, but may lie far to the right of this line and may be found outward as far as the axillary margin of the abdomen. The clinical importance of this observation can be readily understood. I have recently observed a case of intermittent hydrops of the gallbladder in which the patient complained of pain in the axillary margin of the hypochondrium (that is, between the hepatic flexure of the colon and the right kidney), and the dye test in this case revealed a distended gallbladder, the fundus of which approached the axillary margin of the chest. In another instance, a palpable and freely movable tumor mass was found in the axillary margin of the right hypochondrium, approaching the right kidney region. Operation revealed a hydrops of the gallbladder. Such a lateral lying gallbladder may cause pain, tenderness or a tumor mass simulating a loose kidney, kidney tumor, tumor of the hepatic flexure or disease about an ascending retrocecal appendix.

Of those gallbladders found below the right hypochondrium and epigastrium, that is, below the level of the second lumbar vertebra, some extended only to the level of the third lumbar vertebra, but a surprisingly great number were found with the fundus approaching the fourth lumbar vertebra or level of the umbilicus and crest of the ilium, and some extended into the lumbosacral angle and to the level of the fifth lumbar vertebra. In most instances the fundus of the gallbladder seemed to point toward the midline of the body and the navel, but in a few instances the fundus was directed outward, approximating the anterior superior spine of the ilium. In one case I found a gallstone lying just above the anterior superior spine. Before giving the dye I had overlooked this stone, as I interpreted it as fecal material in the ascending colon, but the administration of the dye showed the location of the gallbladder and led to a correct diagnosis.

A very striking observation is the fact that the low gallbladders frequently cast their shadows very close to the spine and in some instances overlap the spine. Certainly, many gallstones have been overlooked in the past, being obscured by the shadows of the spine. This brings us to a very important point in technic. In all the cases included in this series, the roentgen-ray examination was made with the patient lying prone, and the tube was centered vertically over the gallbladder, which would avoid any upward or downward (cephalad or caudad) projection of the gallbladder shadow. However, in order to avoid superimposition of the shadow of the spine on the shadow of the gallbladder, it was necessary in many instances to rotate the body slightly to the left. In spite of this position, however, we still obtained some gallbladder shadows partly obscured by the shadow of the spine, which would prove that a large percentage of gallstone shadows have been obscured in this way.

To determine the range of mobility of the gallbladder, films were made also in the supine and erect postures. A comparison with the routine films made prone showed that the gallbladder moves upward from one-half to 1 inch, when the patient changes from the prone to the supine position. When the patient assumes the erect posture, the gallbladder descends from 1 inch to 1½ inches. This excursion of the gallbladder is least in well nourished or stout persons having good muscular tone. In the thin, relaxed persons, the difference between the erect and the recumbent postures is often surprisingly great, sometimes as much as 3 or 4 inches. Of course, a certain part of the excursion of the gallbladder is due to the movement of the liver and diaphragm, which always accompanies changes in posture.

A diseased gallbladder whose fundus reaches to or extends below the navel may clinically simulate a diseased appendix. Routine roentgen-ray examinations of the colon have shown us that the appendix is usually much below McBurney's point and in most instances is seen deep in the pelvis, but a diseased appendix may refer its pain to the umbilical region, which will explain the frequent difficulty in differentiating gallbladder and appendix disease.

A very low gallbladder, if diseased, may even simulate disease of the right ovary.

The fact that gallstones may be found below the right hypochondrium and epigastrium is not a new observation. Carman, in his book on "The Roentgen Diagnosis of Diseases of the Alimentary Tract," which was written before the introduction of the roentgen-ray visualization of the gallbladder, states that gallstones may be found as low as the crest of the right ilium, and that the entire region from the ribs to the ilium should be covered. However, I do not believe that the great variation of the position of the gallbladder has been sufficiently emphasized, as it was formerly not possible to obtain and to study the gallbladder outline under normal conditions.

Students have been taught to palpate the gallbladder high under the ribs. Roentgen-ray operators, in making fluoroscopic palpations of the abdomen, usually palpate too high for the gallbladder. Fluoroscopic palpations are very valuable diagnostic procedures, especially if the colon is filled by a previous barium meal. The location of the transverse colon, whether high or low, will be the dividing line between the gallbladder region and the appendix region. The hepatic flexure is not a safe guide, as the gallbladder will frequently descend along the mesial aspect of the hepatic flexure to come in contact with a sagging transverse colon.

The variations in the position of the gallbladder are of importance chiefly to the clinician. The surgeon has his landmarks to guide him and will readily find the gallbladder irrespective of its location. The surgeon states that he usually is obliged to pull the gallbladder from under the liver; but at operation the patient is supine and (except when local anesthesia is used) is unconscious. It is, furthermore, likely that preparation for operation, nervous excitement, fasting, struggling or some action of the anesthetic may explain the small, high, contracted gallbladder so frequently observed at operation. It is interesting to note in this connection that before the introduction of the bismuth meal, no surgeon had noted or commented on the position of the normal stomach, as we now understand it.

If the tetra-iodophenolphthalein method of gallbladder visualization does nothing more than to give us the size, shape and position of the gallbladder, it will serve an important purpose in gallbladder diagnoses; but this method has a much wider clinical application.

We are now employing this method as a routine in every complete abdominal examination and are obtaining gallbladder outlines in 90 per cent. of the normal cases. From the standpoint of exclusion (and many roentgen-ray abdominal diagnoses are made partly by exclusion), the clinical value and importance of being able to see the location, size and shape of the gallbladder can hardly be overestimated. In many cases (although not in all) the location of the patient's pain bears a direct relation to the location of his lesion, and the location of the gallbladder with reference to the location of the pain can thus be determined. In another group of cases, a tender point in the abdomen will correspond with the location of the lesion, and the position of the gallbladder with reference to the tender point can be studied. In another group of cases, there may be a palpable abdominal tumor present, and again this method will enable us to determine the relation of the gallbladder to the location of the tumor mass.

It frequently happens that a shadow appears on the roentgenogram that cannot be identified. By obtaining an outline of the gallbladder, we can note whether this shadow corresponds with the position of the gallbladder. If the suspicious shadow corresponds with the shadow of the gallbladder, oblique and lateral views can be made in order to prove whether the shadow falls within the gallbladder outline or whether in front of or behind it. If the suspicious shadow does not correspond in location with the gallbladder shadow, gallstone is immediately and positively excluded.

Since the dye does not enter the gallbladder freely in the presence of a lesion of the gallbladder or bile ducts, the clinical deductions above mentioned may not always be possible. Frequently we obtain only a very faint gallbladder outline which must be carefully searched for, and such a faint outline is always suggestive of a gallbladder lesion. A total absence of the gallbladder outline will prevent the carrying out of the foregoing tests, but the absence of the gallbladder shadow points, in itself, to the gallbladder or liver as the possible site of the lesion.

In those cases in which we have obtained no shadows in the gallbladder region suspicious of gallstones and in which the tetra-iodophenolphthalein test has given a very distinct outline of the gallbladder, and which appears of average size (that is, not unduly distended or contracted) and which does not appear deformed or irregular, we have felt safe in reporting a normal gallbladder. Great distention of the gallbladder would indicate a hydrops. Deformity of the outline would indicate inflammatory changes in the walls of the gallbladder or possibly adhesions about the gallbladder. We have recently seen several cases in which it was horizontally placed and badly deformed, and in which operation revealed a diseased gallbladder adherent to the under surface of the liver. A very interesting condition is that in which the gallbladder outline shows only faintly and is not of uniform density, showing one or more dark areas. These dark areas have been proved to be transparent gallstones which prevent the dye from completely filling out the gallbladder.

When the gallbladder shows only faintly or fails to show at all, our suspicion is directed to it, although we cannot immediately make a diagnosis of a gallbladder lesion without further study. Advanced disease of the liver, such as cirrhosis (which would prevent the normal secretion of the bile) must be first excluded. Then, the failure of the gallbladder to fill with the dye may be due to obstruction of the bile passages by a stone, by thickened mucus or by swollen or edematous walls. The presence of inspissated mucus or bile in the gallbladder would prevent the dye from entering. When the gallbladder fails to fill with the dye, the test should be repeated in order to check up the findings and in special cases, when the clinical aspects of the case do not seem to confirm the diagnosis of a gallbladder lesion, the intravenous injection of the dye may be resorted to. If diseases of the other abdominal organs have been excluded, as far as is possible by the roentgen ray and by a thorough clinical examination, the failure of the gallbladder to visualize, would justify a diagnosis of a gallbladder lesion, especially if the patient presents a confirmatory clinical history. A close coöperation between the clinician and the roentgenologist is essential for a correct diagnosis, as is true of all roentgen-ray work.

The fact that in approximately 10 per cent. of the normal cases the gallbladder may fail to show would lead to a possible error of 10 per cent. Repetition of the test in doubtful cases may, however, reduce this percentage of error. It is furthermore possible, that some of the gallbladders which visualize and are reported normal may be found to be diseased, which fact may increase the chance of error. Much clinical study and further statistical observation are necessary before the final diagnostic accuracy of this method can be definitely stated.

Of those cases in my own series which were reported normal and which later came to operation, no errors have been noted up to this time, although only a small percentage have been checked by operation. Of those cases in which the gallbladder failed to visualize and a gallbladder lesion was reported, only one error has been noted, although again the percentage of cases in which operation has been performed has not been very great. In all of the operative cases in which gallstones were reported, gallstones have been found.

One strikingly uniform observation in my series of cases, which would seem to prove the basic rule that abnormal or diseased gallbladders do not fill with the dye as completely and uniformly as do the normal gallbladders, *is the fact that in those cases in which a preliminary roentgenogram has shown the presence of gallstones,* the subsequent dye test would either show a failure of the gallbladder to fill or would reveal a faint and incompletely visualized gallbladder. When the gallstone blocks the cystic duct, the failure of the gallbladder to fill may be purely mechanical, but in the many gallstone cases in which the ducts are not blocked, the failure of the gallbladder to show in the usual way must be attributed to associated disease of the gallbladder or bile passages.

Further evidence on this point has been obtained from a study of the results of the dye test when made on slightly or deeply jaundiced patients. It has been our uniform finding that the gallbladder will fail to visualize in the presence of jaundice, irrespective of whether the jaundice is obstructive or infectious. In this connection it may be well to bring out the fact that no untoward effects have been observed following the administration of the dye to jaundiced patients.

Prior to the introduction of the tetra-iodophenolphthalein test, roentgenologists have attempted to diagnose gallbladder disease by obtaining a faint outline of the gallbladder. When the gallbladder outline was visible, a thickened or distended gallbladder was reported. In order to test the accuracy of this method, we have attempted to identify the gallbladder shadow on the preliminary film, then checking the finding after administering the dye. In the majority of instances, the preliminary identification of the gallbladder shadow was incorrect, and often the gallbladder was located some distance from the suspected shadow. It is therefore apparent that many inaccuracies have in the past attended such a method of diagnosis. The use of a small cone (as was formerly recommended) would, for obvious reasons, increase the chance of error.

In every case in which the gallbladder fails to visualize, it is of prime importance to make an immediate fluoroscopic examination of the abdomen to search for undissolved capsules. Irrespective of the type of coating used, it frequently happens that the capsules will fail to dissolve. If the majority of the capsules are undissolved, the test should be repeated a second or even a third time. We have thus been able to visualize gallbladders in certain cases in which a cholecystitis had been erroneously diagnosed on the basis of a supposedly absent gallbladder shadow.

Irrespective of the thickness of the abdomen, all roentgenograms of the dye-filled gallbladder have shown an unusually distinct outline of the right kidney, due possibly to the presence of a small amount of the dye in the kidney. The relations of the gallbladder shadow to that of the right kidney have been so varied as to deserve comment. The gallbladder shadow may be well above the kidney shadow, may lie directly in front of the renal pelvis, or may be mesial or external to the kidney outline. Not infrequently, however, the gallbladder shadow has been found to be well below the renal pelvis or even below the lower pole of the kidney. Gallstone shadows may, therefore, be much lower than shadows of renal calculi.

Certain patients in this series have presented, as their chief complaint, pain in the right hypochondrium or directly under the right rib margin, suggesting gallbladder disease. In [illegible] of such cases an apparently normal [illegible] has been found at or near the level of the navel and quite a distance below the site of the pain. In many of these cases the completed roentgen-ray examination has revealed nothing abnormal except a general visceroptosis. The pain in the hypochondrium must, therefore, be attributed to traction of the prolapsed viscera. The dye test will thus serve to exclude gallbladder disease in this very prevalent type of case.

MIXED CELL TUMOR OF THE PALATE

REPORT OF CASE *

G. V. BOYKO, D.D.S.
PASSAIC, N. J.

Tumors of the palate, composed in part of epithelial-like cells, with noteworthy hyaline and mucoid degeneration of both these cells and the connective tissue framework, frequently have been classified as endotheliomas, especially by the earlier writers. The tendency now is to consider them as arising from the embryonic clefts. It is also generally believed that they consist of epithelial cells with varying proportions of connective tissue, cartilage and other tissues characteristic of this region. They are for the most part benign, since as a rule they do not infiltrate, are encapsulated and do not produce metastases.

REPORT OF CASE

History.—A woman, aged 32, came to the surgery clinic of Northwestern University Dental School, Feb. 13, 1925, for advice concerning a swelling of the palate of four years' duration. At first no larger than a small marble, it gradually increased in size, but at no time did it give rise to actual pain or soreness. From a place to the right of the midline and opposite the molar region, it spread in all directions until it occupied most of the space between the molar teeth. About two years before she was admitted, the patient consulted a physician, who lanced this swelling, producing a flow of blood that lasted for several minutes. Since that time, the mass had increased in size, as before, but it was not until three or four months before we saw her that the tumor, because of its size, became embarassing.

Examination.—A tumor mass, with a smooth covering of mucous membrane and about the size of a large walnut, extended from the gingival border of the right molars to within one-fourth inch (6 mm.) of the left molars, and from the posterior extremity of the hard palate to within 1 inch (25 mm.) of the gingival border of the incisors. There was an overlapping of the sides of the tumor against the teeth and the tissues of the palate and it was neither painful nor tender. There was no evidence of any metastasis, and the patient was otherwise in good health.

---

* Read before the Section on Stomatology at the Seventy-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., May, 1925.

Operation.—The patient was admitted to St. Luke's Hospital, Chicago, February 26, and the tumor was shelled out *en masse* on the following day under ether spray, general anesthesia by Dr. H. A. Potts. It was necessary to remove a considerable portion of the mucous membrane of the palate with the tumor; the site of the tumor was allowed to fill in with granulation tissue over which epithelium gradually spread. The tumor mass was enclosed by a fibrous tissue capsule and was attached to the palate by a flat, wide pedicle to the right of the median line. At this place, there was noteworthy absorption of the bone of the palate; in the center of this region, the bone was entirely missing and this defect was 3 mm. in diameter.

Microscopic Examination.—Sections of this tumor stained with hematoxylin and eosin, hematoxylin and van Gieson's fluid, contained nodules and cords of round and oval epithelial cells in an abundant connective tissue framework. In places, the intercellular substance of the connective tissue matrix was so abundant as to form distinct bands. There were many regions of mucoid degeneration which took the blue stain in a diffuse manner. In such regions, the epithelial cells were swollen and the nuclei were crowded toward the periphery of the cell. In other places, these cells had an arrangement suggestive of gland forms. No mitotic figures were seen. Blood vessels were abundant and comparatively large.

SUMMARY

Although this tumor did not contain the variety of tissues found in the mixed tumors of the mouth, it seemed to belong to this group. Its unilateral origin, the tendency of the cells to undergo hyaline and mucoid degeneration and the arrangement of the epithelial cells in cords, nodules and even glandlike aggregations all are in favor of such an identity. Such tumors, while primarily benign, occasionally become malignant; on this account alone they should be removed as early as possible.

ABSTRACT OF DISCUSSION

Dr. George M. Dorrance, Philadelphia: If we study the normal roof of the palate microscopically, we shall notice that there is a large area of fibrous tissue surrounding the little glands in the roof of the mouth. It is quite easy to conceive that, as in the other type of tissue elsewhere in the body, this is glandular tissue surrounded by fibrous tissue. These tumors have not been satisfactorily classified. We used to call them fibromas. I do not think that tumors can be classified to suit all of us. It is hard to be dogmatic and say that it is a fibroma, an adenoma or a myoma. We are pretty sure when it is a carcinoma, but we are not sure of the other tumors. The treatment of this case is ideal. The tumor was taken out entirely, and more than likely there will be no recurrence. At the Philadelphia General Hospital, where we have a group of seven men, including a roentgenologist and a pathologist, we are continually having discussions as to where to classify these tumors. Until such time as the pathologists and the clinicians agree, we shall have to classify them with the old group of fibromas and adenomas. However, I find that these tumors are very rare. The ordinary osteoma is common. The results of this seem to me to follow along with hypertrophy of the gums. We do not know what causes hypertrophy of the gums. We know when it occurs, we remove the tumors completely and they do not return. The same is true of this tumor.

Dr. Robert H. Ivy, Philadelphia: My experience has been limited to two tumors of this type, one confined to the soft palate and the other to the hard palate. Both of them exhibited microscopic characteristics identical with this one of Dr. Boyko's. The sections from the first tumor, which occurred about twelve years ago, were submitted to practically all the leading pathologists in Philadelphia, and there was great disagreement as to what it was. Several of them felt that it was endotheliomatous in nature, and it was as such that I reported the tumor, but I feel convinced now that these cells are epithelial and that we must not classify them as endotheliomas, in which group a great many tumors have been put when they could not be definitely assigned elsewhere.

Dr. F. A. Figi, Rochester, Minn.: I hardly see how this tumor can be classified as either an adenoma or a fibroma. The possibility of considering it a fibroma is ruled out by the marked preponderance of epithelial elements present, while the atypical character of these cells precludes its being an adenoma. I would say rather that it was a mixed tumor or an adenocarcinoma. Both of these frequently occur in this region, and both are comparatively benign types of malignant tumor. They are both definitely malignant, however. They may occur either in the hard or in the soft palate and often reach an enormous size. We have removed them from this region as large as 8 or 9 cm. in diameter, after ligation of the external carotid artery on either side. I think this case was handled ideally from the standpoint of treatment.

Dr. Edward H. Hatton, Chicago: The fact should not be lost sight of that the structures of the palate and the parotid region of the neck, and to a less degree of the lips and the tongue, are intimately connected with the embryonic gill clefts, and that in the closing of these gill clefts abundant opportunity is offered for the deposition of cell rests containing rudimentary epithelium, cartilage, fibrous tissue and sometimes glands. Tumors arising from these rests are unilateral, slow growing, stimulated to growth at the time of puberty or afterward, and develop much as this one did. On this account I am inclined to believe that the mixed cell classification is correct and that these cells are epithelial cells.

Dr. Carl W. Waldron, Minneapolis: My experience has been limited to two cases, both of which were somewhat interesting. In one case, the mixed tumor of the palate was no larger than the diameter of a fountain pen it was situated in the center of the hard palate at about the junction of the maxillary and palatal bones. It had developed slowly over a period of three or four years at the site of an injury made by a lead pencil some fifteen years before. It was very readily removed without recurrence. The other case was a somewhat unusual one. A patient came to our clinic with very marked protrusion of the upper six anterior teeth, so marked that the upper lip was forced upward beneath the nose, and the lip could not be closed, even on strongest muscular effort. The whole anterior portion of the alveolar process with the teeth was resected *en masse*, and a very favorable result from the standpoint of a denture was secured. About a year later she returned, complaining that the denture did not feel comfortable posteriorly on the palatal side of the tuberosity. At this site she had been operated on twice previously and had been told that there was dead bone. Fortunately, at the first appearance of the patient, we took a cast of this unusual deformity, which showed a slight asymmetry in this palatal region. On reexamination, this asymmetry was more pronounced. Palpation seemed to show very definite fluctuation, and on incision some material came away, not a liquid exudate or purulence, but rather like softened lymphoid tissue, such as one might encounter on incising a tonsil capsule after its removal in a broken down tonsil. I collected this for examination, and the report was a mixed tumor. I operated again a week or two later, but in this instance the swelling was so small that to the best of my ability I could not determine a capsule, so I excised, I felt, sufficiently widely to remove the tumor. However, it may be subject to recurrence, and I shall check it up as soon as I return.

Dr. G. V. Boyko, Passaic, N. J.: As Dr.Hatton has brought out in his discussion, the characteristic structure of this tumor and the fact that there is no definite classification for it make it seem most appropriate to place it in the "mixed tumor" class.

Smallpox in Connecticut.—During the years 1923 and 1924, 152 cases of smallpox with six deaths were reported in Connecticut. Five of these deaths occurred in persons who had never been successfully vaccinated and one had been vaccinated more than seven years before onset. In the first group mentioned there were ninety-six cases; in the second group, twenty-four cases. One patient had had smallpox previously, and three patients had been vaccinated within seven years.—*Pub. Health Rep.* **40**:1811 (Aug. 28) 1925.

NUTRITIONAL KERATOMALACIA

REPORT OF CASE

A. B. SCHWARTZ, M.D.
MILWAUKEE

The occurrence of keratomalacia as a result of faulty diet has been established for human beings as well as for animals.[1] While numerous observers realized early that the disease had something to do with nutrition, and many conceived a definite relationship to the diet, it was not until the striking animal experiments of McCollum and his co-workers,[2] and those of Osborne and Mendel,[3] that this disease could be classified as an avitaminosis. It is now generally conceded that it is essentially a deficiency disease following deprivation of the fat soluble A vitamin. Groups of cases as have been described have generally occurred in periods of famine or in countries having grossly inadequate food resources. The large series of cases collected by the Danish Ophthalmological Society during the period from 1909 to 1920[4] were attributed to the peculiar circumstance of a dairy country exporting the most important products providing the fat soluble A factor.

McCollum's[5] recent experiments indicate that other factors besides the amount of fat soluble A contribute to the production of this disease. The total amount of salt mixture and its composition is an important factor. The interrelationship between certain nutritive principles in the dietary may play a rôle. These experiments may explain the occurrence of keratomalacia in infants who have not been completely deprived of fat soluble A. Thus, the patients reported by Ross[6] had had previous diets of condensed milk, a food not entirely lacking in this specific vitamin.

A study of the literature reveals numerous similar instances. Very frequently the history of previous digestive disturbance is reported. That functional disturbance of the digestive tract produces changes in the intermediary metabolism is well recognized. Meyer[7] found a negative salt balance in infants suffering from dyspepsia and receiving a low fat diet.

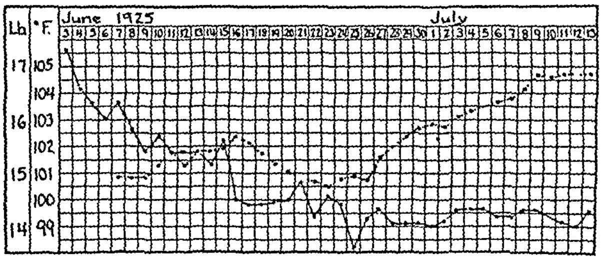
Some students of the disease distinguish several types, depending on whether the vitamin A deficiency has been the sole cause of the disease or whether other factors are also involved.

Bloch[8] identifies three types: (*a*) xerophthalmia with carbohydrate dystrophy; (*b*) xerophthalmia with carbohydrate atrophy, and (*c*) a group in which he realized that the symptoms were due to complete absence of fat substances which he termed dystrophia alipogenetica. He was then unacquainted with McCollum's work. The first two groups gave nutritional pictures corresponding to the "mehlnährschaden" of Czerny, and Bloch entertained the possibility of this being an avitaminosis in a class by itself.

Stransky[9] divided keratomalacia into two classes, one in which there is a definite avitaminosis caused by the entire absence of fat soluble A vitamin and which corresponds to experimental keratomalacia. He regards the term hypovitaminosis as more suitable for those cases in which the body's available supply has been disturbed by infection or by quantitative inanition.

In this country the universal availability of milk as a basis for infant feeding probably accounts for the rare incidence of the disease. It is interesting to note that in the years from 1890 to 1894, Kollock[10] of South Carolina observed numerous instances of the disease among the negroes. These observations formed the basis of several reports to the American Ophthalmological Society. Kollock noted that it was more common among the blacks than the mulattoes. He recognized that dietary factors played a part, noting that "the negro lived commonly on hominy (grits), rice, fish and bad hog meat," and thought that "the diet may have something to do with the condition." Kollock[11] reports that the disease is rarely observed at the present time.

Besides Kollock's observation, there have been isolated clinical reports in American medical literature by Weeks,[12] in 1887, Evans,[13] in 1898, and Little,[14] in 1882. More recently, Ross[6] reported four cases from the Children's Department of the Johns Hopkins Hospital, and DuBois and Wilson[15] reported one case from the Boston Infants' Hospital. All of these patients died from the disease.



Temperature and weight curve, showing period of three weeks' treatment before temperature (solid line) reached normal or weight (dotted line) increased.

REPORT OF CASE

The present report is one of keratomalacia following a diet therapeutically restricted, constituting virtually an experimental production of the disease.

A. J., an infant boy, had been breast fed until 10 months of age. Occasionally, besides breast milk, he received toast or buttered bread. Between the sixth and eighth months, during the past winter, he had had two bowel upsets, both occurring during a month's interval. These were cured by restricting his feedings.

The present illness began, May 12, 1925, with fever, restlessness, constipation and a slight cough. On the third day of the illness, he was reported as having had a "toxic dyspnea" and "looked as though he were going to die." This condition cleared up in thirty-six hours. After a few days his condition

became worse again. He had no more dyspnea, but had very intractable constipation, which took castor oil and frequent flushings to modify. Besides the constipation, the only other symptom that impressed the parents was the infant's stupor.

The diet instituted on the first day of illness was oatmeal water and Mellin's Food in water. Both of these were given in small quantities about every hour or two. This constituted the entire diet regimen from May 12 to June 3, a period of twenty-two days, after which the baby was admitted to the Milwaukee Infants' Hospital.

On admission, the infant presented the semistuporous appearance of a typhoid or miliary tuberculosis, not the acutely ill facies of an intestinal intoxication. The eyes were held closed most of the time. The skin was doughy, the musculature flabby and the approximate weight loss since the onset of illness about 6 pounds (2.7 kg.). The mouth was dry and congested and the lips were cracked. No generalized adenopathy was found. The heart and lungs were apparently normal, the abdomen was distended and the visceral pattern very distinct. The throat was reddened. The ear drums were normal. The liver edge seemed very sharp and firm; the spleen was not felt. There was no rigidity of the extremities or of the neck. The reflexes were not abnormal. The fingers appeared slightly cyanosed. The temperature, on admission (4 p. m.), was 105.6. The provisional diagnoses were: (1) erythredema; (2) typhoid fever, and (3) miliary tuberculosis.

The urine showed a trace of albumin, and the microscopic examination was negative. Blood examination showed: 4,800,000 red blood cells; 85 per cent. hemoglobin (Tallqvist); 13,500 leukocytes; 78 per cent. polymorphonuclears, and 22 per cent. large lymphocytes. The Pirquet reaction was negative. Intracutaneous injection of tuberculin (0.01 mg.) was negative. The Widal test was negative. Spinal fluid examination revealed: no increased pressure; clear fluid; no cells; globulin negative and the sugar reduction diminished.

During the first twenty-four hours of his hospital stay the infant was given about 8 ounces (236 c.c.) of fat free lactic acid milk containing two-thirds ounce (20 c.c.) of Karo Corn Syrup. He seemed rather eager for this feeding but vomited a large part of it. Toward the end of the twenty-four hour period, he began to retain more of his food.

June 4, the temperature ranged from 101 to 104, and the baby was in a drowsy stupor. The legs were held in a froglike position, and the baby cried when they were touched or lifted. On the abdominal wall, to the left of the umbilicus, were several pin point petechial spots, probably the result of scratching. The possibility of scurvy suggested itself. The spots cleared up after a few days. Both eyes were dull in appearance, the sclerae yellow tinged, the right eye showing a corneal ulcer.

June 5, the child was in a stupor all the time, occasionally giving a sudden cerebral cry, accompanied by fixation of the eyes and rigidity of the upper extremities lasting only a few seconds—a miniature convulsion. The breathing was regular and quiet. There was a very slight suggestion of neck rigidity, and no rigidity of the extremities. The abdomen was distended. The cyanosis of the hands had disappeared. Spinal fluid examination was negative. The corneal ulcer was more distinct.

A diagnosis of keratomalacia being made, the food was changed to whole lactic acid milk, and 10 drops of cod liver oil three times daily was ordered. One ounce (30 c.c.) of orange juice was given twice daily.

Eye examination by Dr. Haessler revealed a large loss of substance in the cornea of the right eye, 4 mm. in diameter, involving one half of the depth of the cornea, with almost no marginal infiltration. Minimal hyperemia of the conjunctiva and no demonstrable ciliary hyperemia were discovered. The remainder of the cornea was clear, though the epithelial surface was slightly dull and distinctly less sensitive to mechanical stimuli than normal. The pupil did not dilate under homatropin, but the corneal defect would preclude ophthalmoscopic examination.

The corneal surface of the left eye was dull and less sensitive than normal and seemed slightly dry and stippled. A very faint nebula was seen in stroma by oblique illumination and was more evident by transmitted light. The fundus seen through a 5 mm. pupil (homatropin) was essentially normal. A slight haze of nerve head margin was ascribed to the effect of corneal imperfection. The diagnosis was trophic corneal lesion (xerophthalmia).

June 6, the patient was less drowsy, but kept his eyes closed and fretted while being examined. He cried out occasionally as though in pain. He took his feedings willingly. Though the tongue looked parched and dry, the mouth condition was slightly improved. The abdominal distention was less pronounced and the tissue turgor poor.

June 7, the child moved his hands to his mouth constantly, and seemed much fussier and more fretful when his legs were moved, the left one particularly distressing him. Examination of the right eye revealed the ulcer edge to be deeply infiltrated with heavy white margin, and the hyperemia markedly increased.

Cod liver oil, 1 c.c. hypodermically, was given daily.

June 8, the ulcer edge of the right eye was not greatly changed. As the center of the ulcer bulged moderately, a pressure bandage was applied.

Blood examination revealed: white blood cells, 11,500; polymorphonuclears, 64 per cent.; large lymphocytes, 30 per cent.; transitionals, 6 per cent. The urine was acid, with a trace of albumin; the microscopic examination was negative.

The next day there was not much change in the condition. The child fretted a great deal, and lay with his legs in a froglike position (infiltration of tissue due to hypodermic cod liver oil?). A roentgenogram of the extremities showed mild rickets. Examination of the right eye showed the ulcer edge heavily infiltrated with leukocytes. The child seemed much soothed when the eye was compressed.

The general condition was improved, June 10. The child was very fussy, but behaved in a more natural manner. The first weight gain was noticed, the present weight being 15 pounds, 3 ounces (6.8 kg.). The right eye was sunken; the left eye showed a normal luster with the corneal reflex normal.

June 13, the cod liver oil by hypodermic was omitted, and one-half teaspoonful, three times daily, ordered.

June 15, the child fussed a great deal when disturbed, but this might have been due to the great amount of induration that was present at the points of injection of the cod liver oil. He was quiet unless disturbed. The general condition was improved. Examination showed no rigidity of the neck or of the extremities. The liver edge felt much softer on palpation. The mouth was clean and moist; the cracks in the lips had healed.

Eight days later, when quartz lamp exposure was begun, the temperature dropped from 102.2 to 98.2, and for the rest of the hospital stay rarely exceeded 100.

The condition remained stationary for about ten days. The child took food very poorly and vomited feedings if they were urged. The bowels remained normal, with a slight tendency to constipation. The child fussed a great deal, particularly if disturbed.

June 26, with no changes in diet, the infant gained in weight. After this, he became much happier, took feedings eagerly, and convalescence progressed without further event, as shown in the accompanying chart.

COMMENT

This case presents a number of unusual features. The appearance of keratomalacia three weeks after the apparent deprivation of fat soluble A constitutes a startlingly rapid development of the disease. While in animal experimentation such rapid development frequently obtains, there one is dealing with a different life cycle. One might assume some comparative diet deficiency during the time preceding the actual onset of the symptoms, but in this case the infant was said to have been in perfect health prior to the onset of the illness.

The study of the clinical history reveals in this instance a rather unusual manifestation of nervous symptoms. The first impression, on examination of this patient, was the presence of disease of the nervous system. In the differential diagnosis, the following diseases were considered: erythredema, typhoid fever, tuberculous meningitis, scurvy and encephalitis. There was a very definite suggestion of cerebral irritation. In a study of the literature, this appearance of nervous symptoms has been not infrequently noted. As early as 1866, von Graefe,[16] who gave the first accurate description of the eye symptoms, mentioned, as general symptoms, pallor, diminished tonus, poor digestion and anorexia, but no striking cerebral symptoms. This was mentioned because of one case, particularly, in which the patient had convulsions and lethargy preceding death. Klebs [17] found an encephalitis on postmortem examination. Later observers discounted these early reports of encephalitis. Schulz [18] reported a case showing mild convulsions, the head in opisthotonos and marked rigidity of the neck. On postmortem examination, the brain was normal. Stephenson [19] noted opisthotonos in five out of thirty-one cases seen by him, but in one alone was there meningitis, as proved by postmortem examination. Bloch [8] describes the infants in his Type B classification as very fretful and sensitive to outside impressions. Stolte [20] not only observed hyperirritability, but noticed that some who recovered later had spasmophilia. Of Ross' [6] reported cases, opisthotonos and neck rigidity were noticed in Cases 3 and 4.

The outstanding symptoms of this patient were stupor, irritability on being disturbed, weight loss and other evidences of nutritional disturbance (pallor, doughy skin), dry inflamed mouth and cracked lips, fever, and the characteristic corneal ulceration. The liver seemed unusually large and firm when the child was first seen. The symptoms suggestive of meningeal disturbance persisted for a number of days. Besides the symptoms in the case report, it should be mentioned that transient strabismus was observed the day preceding hospital admission. Spinal fluid examination showed no pleocytosis nor increased globulin. There was slightly diminished sugar reduction. The child lay in the froglike position occasionally observed in scurvy. As the child had had intragluteal hypodermic medication, it was hard to rule this out as a factor in the position assumed.

The patient showed complete recovery, except for the loss of vision in the right eye. The response to the treatment with fat soluble A substance in this patient with keratomalacia was not nearly so striking as that often witnessed in scurvy following the use of orange juice. Despite the hypodermic administration of cod liver oil as suggested by Bloch, convalescence was slow. The absorption of cod liver oil thus given was very slow. It was three weeks after specific treatment was begun before the weight curve and the other symptoms showed appreciable change. It is very obvious that the appearance of the characteristic eye changes are ominous of more advanced nutritional disturbance than is apparent. Wolbach's [21] investigation leads one to believe that the changes undergone by the experimental subjects of this disease are more generalized than have heretofore been assumed. Wolbach found a considerable degree of atrophy in all of the epithelial tissues of the body, with ultimate keratinization of these tissues.

SUMMARY

1. The occurrence of keratomalacia in an infant following a diet restricted for therapeutic purposes constitutes an almost experimental production of the disease.
2. Besides the usual weight loss and nutritional upset, the infant presented pronounced meningeal symptoms.
3. The patient recovered following the administration of cod liver oil, given by mouth and hypodermically, and a diet of whole lactic acid milk.

418 East North Avenue.

THE TREATMENT OF ERYTHREMIA WITH PHENYLHYDRAZIN *

TREVOR OWEN, M.B.
BALTIMORE

In a previous paper,[1] a case of polycythemia was reported which had been under treatment with phenylhydrazin hydrochlorid. Since the result in that case was so satisfactory, and since none of the other methods of treatment for this disease have been more than temporarily beneficial, it seems desirable to record the observations in four more cases treated with this drug in order that its actual value may be finally estimated. As I pointed out in the first paper, phenylhydrazin was used by Morowitz and Pratt to produce secondary anemia in animals, after which Eppinger suggested its use in the treatment of erythremia. Later, Taschenberg experimented with the drug in one patient. The results obtained in their cases were not successful, probably because the patients were in a late stage of the disease.

If phenylhydrazin proves of benefit in the treatment of the disease, it is important, because by the time patients with erythremia are compelled by their symptoms to ask a physician's advice, the problem is not so much one of diagnosis as of therapeusis. Previously, even with the combination of frequent bleedings and roentgen-ray or radium application, the certainty of being able to reduce the red cells and hemoglobin to somewhere within normal limits and to keep them there has been a difficult and sometimes impossible task.

The subsequent course of the case referred to (Case 3) can now be given, together with the results of treatment by phenylhydrazin of four other cases of erythremia.

The first two patients were treated by Dr. John L. Dorsey of Baltimore and, as far as I know, are the earliest ones to receive the drug in this country. He has kindly allowed me to include them in this report.

Case 1.—A woman, aged 60, who had a true polycythemia of some years' standing, seen, April 13, 1923, complained of increasingly severe headaches and pains in the fingers. She presented a typical picture of the disease with a large spleen. The red blood count was 10,112,000; the white cells, 5,000, and the hemoglobin, 120 per cent. (Dare). During April, 1923, she was given four radium treatments with no apparent benefit and no change in the blood count. May 22, 1923, she began a course of phenylhydrazin in 0.1 gm. doses daily for twenty days. This was given in capsules by mouth.

Table 1 shows the dosage and the variations in the blood counts during treatment in this patient.

5/17	0.1 gm. daily for 5 doses					
6/ 9	0.1 gm. daily for 5 doses	108	4,960,000	5,000	..	

The facts to be particularly noted in the table are that the polymorphonuclear percentage was usually high; a mild secondary anemia occurred once, and there was always an exacerbation of the symptoms whenever the blood count rose.

It will be seen that 2.6 gm. was originally required to bring the blood down to normal, the count gradually falling for three weeks after the drug had been stopped. Three months elapsed before a resumption of treatment was necessary, after which the drug was given as indicated. In these twenty-five months, a total of 14.1 gm. of phenylhydrazin has been used, which is approximately 0.13 gm. a week. There have been no unpleasant symptoms from the drug, and now the patient is in good health.

Case 2.—A widow, aged 60, who had consulted Dr. Dorsey, Dec. 5, 1923, because of pain in the chest, had had bad health for several years. Her husband died in 1903 of cirrhosis of the liver, and she had a nervous breakdown following this trouble. During this time, there was some numbness in the arms. Gradually, she had become more and more easily fatigued. She had an old sinus infection which was kept under observation. There was an appendectomy in 1917. In 1919, some neck ligaments were torn in a motor accident, and she was in bed for several weeks. She suffered from frequent headaches, which were relieved by codein. Several abscessed teeth were removed during the last few years. There was no history of hemorrhages. The family history was negative.

For a few weeks she had been having a sharp pain over the precordium. This did not radiate and was not related to exercise. It frequently woke her up at night with a feeling of oppression. Very frequently she would have a tense aching pain in the fingers.

The patient was a well nourished woman. Her face was slightly red, and the lips, hands and feet were definitely cyanotic. The fundi were normal; the veins not overfull. Around the margin of both disks, there were several areas resembling old hemorrhages or choroidal degeneration. The pharyngeal and buccal mucous membrane was fiery red. A good many dilated veins were present over the sternum. The lungs were clear. The heart was slightly enlarged, the left border being 14 cm. to the left of the median line, and the right border 4 cm. There was definite retromanubrial dulness. The heart sounds were normal except for a gallop rhythm. No murmurs were heard. The radial and brachial arteries were moderately thickened, and the systolic blood pressure was 170; diastolic, 125. The abdomen appeared normal, but the spleen was enlarged and reached to within 6 cm. of the umbilicus. The liver just reached the costal margin. There was edema of the feet. The reflexes everywhere were normal.

The urine varied in specific gravity from 1.010 to 1.020; a trace of albumin and an occasional hyaline cast was present. The phenolsulphonephthalein excretion was 59 per cent. in two hours. The blood examination showed: 8,342,000 red cells; 10,840 white cells, and 122 per cent. hemoglobin (Sahli). There was slight anisocytosis. In the differential count, there were 73.2 per cent. polymorphonuclears and 26.4 per cent. lymphocytes. The platelets were increased. The blood nonprotein nitrogen was 34.2 mg. per hundred cubic centimeters; sugar, 10 mg. per hundred cubic centimeters; uric acid, 3.49 mg. per hundred cubic centimeters; creatinin, 3.0 mg. per hundred cubic centimeters. The Wassermann reaction was negative. The stools were normal. Roentgen-ray examination of the chest showed a moderate enlargement of the heart, a dilated aorta, and a generalized nontuberculous infiltration of both lungs. The diagnosis was erythremia, arteriosclerosis and hypertension.

Table 2 shows the course of this case under treatment. It was carried out while the patient was up and about.

The noteworthy facts shown in Table 2 are: There was always a high polymorphonuclear percentage; a relatively slight leukocytosis occurred; the blood pressure fell to a normal level, and the liver became slightly larger.

In summary, this patient required a total of 12.4 gm. of phenylhydrazin in the seventy-seven weeks, an average of about 0.16 gm. a week, to keep the blood normal. A slight secondary anemia was produced on two occasions, but otherwise the course was uneventful.

Case 3.—A man, aged 46, who had had erythremia probably for ten years, developed neurologic symptoms only five months before coming under observation in December, 1923. Immediately before treatment was begun, the blood examination showed: hemoglobin, 145 per cent.; red blood cells, 7,612,000; leukocytes, 8,000. In the course of three weeks the patient was given 2.4 gm. of phenylhydrazin, with the result that his blood count became normal and he felt well. After discharge from the hospital, there was an exacerbation of his symptoms and another rise in the blood count. This was again easily reduced to normal after another course of the drug in May and June, 1924, during which time he received a total of 1 gm. Since then, a matter of twelve months, he has been followed very carefully and has remained perfectly well. Complete blood counts were made every two weeks for the first few months. As the hemoglobin at the end of this time was 105 per cent. and the red cells 5,500,000, 0.1 gm. doses were given twice in the last two weeks of July, once a week in August, and three times in September. Since then, he has taken 0.1 gm. once a week. On this small but regular dosage, the blood count remained normal until the end of 1924, when a gradual rise was noted. In December, 1924, the hemoglobin was 108; red cells 5,640,000, and the leukocytes 10,800. During January, February and March the counts were reduced slightly. During April, no phenylhydrazin was taken, but in May he took 0.1 gm. every five days and in spite of this, at the end of the month, the red cells were found to be 8,900,000, and the hemoglobin, 115. In June, he took 0.1 gm. every other day with little effect, and by June 19 the hemoglobin was unchanged and the red cells were 7,100,000. A fresh supply of phenylhydrazin was obtained, and he was given 0.1 gm. every day for ten days. This has resulted in complete recovery again, and at the present time of writing (July 29, 1925), the hemoglobin is 100, the red cells 4,360,000 and the white cells 10,000. Though this increase in blood count was accompanied by a return of some of the symptoms, the patient has not had to stop work at any time and has felt perfectly comfortable since beginning treatment.

When these patients are studied by daily counts during the administration of the drug, interesting and important changes take place. The next two patients, who were in the Johns Hopkins Hospital for treatment, illustrate this point.

CASE 4.—S. M., a Russian laborer, aged 62, was admitted Oct. 14, 1924, presenting all the features of a severe grade of polycythemia. His complaints were redness of the hands, headache, weakness and a sensation of internal heat. He was a brilliant purplish red, with dilated veins over the head, neck and arms and to a lesser extent in the legs. He had a large colloid goiter, considerable emphysema, a slightly enlarged heart, moderate thickening of the arteries, and a blood pressure of 160 systolic and 100 diastolic. The liver and spleen were just palpable. There was slight dyspnea and some sweating of the hands and feet. The blood showed 10,000,000 red cells, 8,000 leukocytes and 123 per cent. hemoglobin.

Chart 1 shows the effect of the treatment. This was started, October 31, with daily doses of 0.2 gm. of phenylhydrazin. After twelve days this was discontinued, and urobilinuria, an increased leukocytosis, and a gradual fall in red count and hemoglobin took place. However, this proved to be only of temporary duration, and after a rise in counts another course of the same daily dosage was begun. In three or four days, the hemoglobin and red cells showed a rapid fall. The urobilin became greater, the spleen increased in size and on one day there was pain and a friction rub over it. The drug was not stopped altogether, but the dose was cut down to 0.1 gm. a day for three days, and then discontinued. In this second course, 1.9 gm. had been given. For two weeks, the count kept on falling and reached 5,300,000 red cells and 88 per cent. hemoglobin. During this process, the patient's color became normal, the dyspnea disappeared, and he felt better than he had for many years. He was discharged two months after entry, the blood count then showing 6,000,000 erythrocytes and a hemoglobin of 90 per cent. The blood pressure had fallen to 140 systolic and 74 diastolic.

Supervision of this case could not be carried out as carefully as one would have liked because the patient lived out of the city. At the first, inadequate amounts were given, and in seven weeks with 0.2 gm. a week, the hemoglobin rose to 120 per cent., the red cells to 7,744,000, and the leukocytes to 20,000. During the next two weeks, 1.6 gm. was given with a most satisfactory result. The hemoglobin fell to 88 per cent., the red cells to 6,760,000 and the white cells to 7,000. From that date and for a period of nine weeks, a total of 2 gm. of phenylhydrazin was taken. At the end of that time, May 1, 1925, the hemoglobin was 106 per cent., the red cells 5,724,000 and the white cells 20,000.

In summary, 4.3 gm. of phenylhydrazin was required originally to reduce the blood count to normal. Five weeks after this course was completed, treatment was started again and for seventeen weeks an average weekly dose of approximately 0.3 gm. was necessary to keep the blood count about normal.

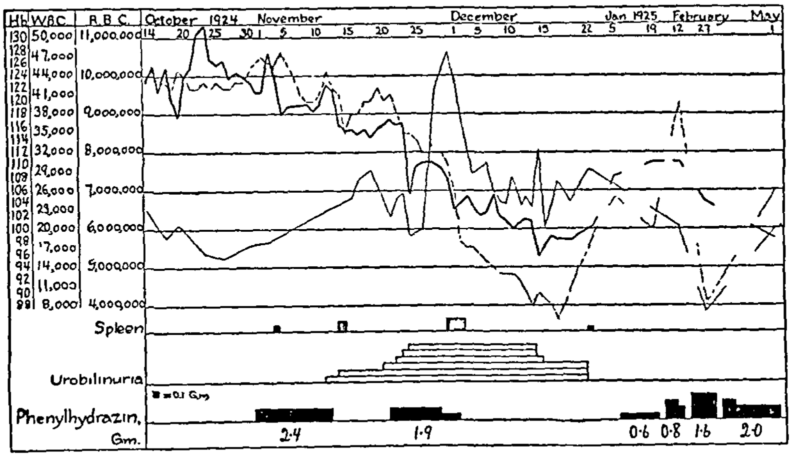

Chart 1 (Case 4).—Effect of doses of phenylhydrazin on blood count: heavy line, *red blood corpuscles; light line, white blood corpuscles; broken line, hemoglobin.*

Case 5.—A man, aged 56, admitted to the Johns Hopkins Hospital, March 19, 1925, had had symptoms for four or five years and complained of attacks of pain in various parts of the body. He was the picture of a polycythemia of a moderate grade. The hemoglobin was 114 per cent.; the red cells 9,224,000 and white cells 18,200; polymorphonuclear cells, 80 per cent. The liver was just palpable, and the firm spleen was three fingerbreadths below the costal margin. The systolic blood pressure was 167; diastolic, 110. He weighed 157 pounds (71.2 kg.). Chart 2 shows the course of Case 5 under treatment. As in Case 4, beginning March 22, 0.2 gm. of phenylhydrazin was given daily for fifteen days, a total of 3 gm. A week after this was started, the hemoglobin and red cells were decreasing rapidly, and the leukocytes were rising. The leukocytosis is important and will be discussed below. After the drug was stopped, a further increase in the leukocytes took place, reaching 59,800 nine days later. As will be seen, a moderate secondary anemia was produced just after this point, the hemoglobin going to 45 per cent., and the red cells to 2,800,000. During this process, jaundice developed, the spleen became smaller, and there was a slight urobilinuria. There was also fever of from 99 to 100, which twice reached 101. The patient felt very weak and lost his appetite completely. There was a persistent cough, and it was thought that he had a bronchitis. Soon after the leukocytosis began to subside, the red cells and the hemoglobin commenced to rise. This did not occur until two weeks after the last dose of phenylhydrazin. On discharge, seven weeks after the first dose, the hemoglobin was 68 per cent., the red cells 4,144,000, and the leukocytes 16,800. The systolic blood pressure was 136; diastolic, 80. The patient was feeling much stronger, was free of pain and had a good appetite. A week later, May 18, the hemoglobin was 80 per cent., the red cells 4,800,000, and the leukocytes 22,000. He was told to have blood counts made every two or three weeks, and as soon as the hemoglobin reached 100, he was to begin taking 0.3 gm. of phenylhydrazin a week, but he was to stop if the leukocytes rose or the hemoglobin fell below 90.

COMMENT

Clinical Course.—An examination of the charts will make it clear that the use of this drug presents two problems. One of these has to do with the rapidity with which the drug can be given, and the other with the duration of its administration. Excessive doses will cause secondary anemia, which, even though temporary, may be sufficiently severe to be alarming. As the drug is not excreted very rapidly, the effect is cumulative. In Cases 1, 2, 3 and 5, the red cell destruction continued for over two weeks after the drug was stopped, while on the other hand, in Case 4 (Chart 1), the first 2.4 gm. was not sufficient to be effective.

In the repeated studies that were made in Cases 4 and 5 shown in Charts 1 and 2, the first effect of the drug which could be observed was an increase in the leukocytes. This occurred before any changes were noticed in the number of red blood cells or in the percentage of hemoglobin. Referring to Chart 1, it can be seen that, on admission, the leukocytes were 23,000, while at rest in bed during the next twelve days, the leukocytes fell to 15,500, the red cells at the same time increasing to 11,300,000. Phenylhydrazin was then begun, and during the first course of the drug the leukocytes rose gradually from 17,200 to 30,000. Soon after this increase in the white blood cells had begun, the hemoglobin and red cells were noticed to fall, and urobilin appeared in the urine. After the drug was stopped, the counts tended to revert to their previous levels. When a second course of phenylhydrazin was begun after an interval of only nine days, there was an abrupt rise in the white count from 19,000 to 47,500. When the dose was reduced, the leukocytes fell again to about 30,000 and the red cells increased.

In Case 5 (Chart 2), twelve days after the first dose, there was a leukocytosis of 24,000, and nine days after the last dose this had increased to 59,000 and a marked decrease in the red cells and hemoglobin followed. It was observed that, in the two cases when daily counts were made, this rise in the leukocytes always preceded the fall in the red cells and hemoglobin, and that the greatest leukocytosis came before the greatest drop in the hemoglobin and red cells. This is also seen most strikingly in Chart 2 of Case 5. With this increase in the leukocytes and the rapid fall of the hemoglobin and red cells, there was a moderate icterus with a slight urobilinuria in Case 5, and a marked urobilinuria with jaundice in Case 4. It was also noticed that, although the leukocytes fell to a lower level after the drug was discontinued, they did not reach normal figures until the red cells and hemoglobin had begun to rise again. In Cases 1 and 2, a leukopenia was found with smaller doses, but when larger amounts were given a leukocytosis occurred. These observations seem to point clearly to the fact that on the administration of phenylhydrazin, a leukocytosis preceded the fall in hemoglobin and red blood cells, and that the reduction of hemoglobin and red blood cells which follows is roughly proportional to the leukocytosis. It is necessary, therefore, to follow the changes in the leukocyte counts when the drug is being given, for an increase in the white cells is an indication for stopping the drug.

The question of the possible causes of the leukocytosis is an interesting one. One might conceive of the leukocytosis as being due to a direct effect of the drug on the bone marrow, or hematopoietic tissue, but such an explanation seems unlikely, in spite of the fact that the bone marrow is hyperplastic in animals poisoned with the drug. A more likely explanation of the leukocytosis might be that it is a compensatory mechanism due to injury which phenylhydrazin causes to the cells of the liver, and certainly to the erythrocytes. With phenylhydrazin administration, a destruction of red blood cells is evidenced by a decrease in their numbers and by urobilinuria, and when large doses are employed, these are so greatly increased with jaundice accompanying them that one suspects liver cell destruction as well. A similar destruction of tissue and especially of the liver may account for the leukocytosis seen in certain cases of acute poisoning with such substances as mercuric chlorid, lead, arsenic and *Amanita phalloides,* and in some cases of acute yellow atrophy. These substances also injure tissue cells, and the leukocytosis may indicate a certain degree of actual necrosis.

In animal experiments with the hydrazin compounds, extensive damage to the liver is known to occur. Wells,[2] studying the organs of dogs, cats and guinea-pigs to which he had given toxic doses of hydrazin, and Underhill and Kleiner,[3] in similar experiments, found very constant changes. The liver alone was usually affected. It was friable and very yellow. In every case, there was fatty degeneration of the cytoplasm of the parenchymatous cells beginning at the center of the lobule and progressing outward. He saw no focal necroses. The statement is also made that the hydrazin had apparently no effect on the red cells because no abnormal pigmentation of the liver cells, spleen or lymph glands was present. Later, Underhill[4] gave dogs large doses of the various hydrazin compounds. No details are recorded, but the following effects were noted: In a 10 kg. dog given a dose of 500 mg. of phenylhydrazin, the liver was of a peculiar chocolate color and the spleen enormously enlarged and dark purple.

Methylphenylhydrazin had no effect on rabbits, and in a dog weighing 4 kg., which received 200 mg., the organs were uninjured. The same was true of diphenylhydrazin and semicarbazid. Bodansky[5] made a study of the same kind, estimating the amount of liver damage by sugar tolerance tests. His observations are in agreement with the previous ones, but examinations of the organs are given in more detail. Unlike Wells, he did find areas of necrosis in the liver. The importance of these experiments lies in the fact that some of the derivatives of hydrazin are less destructive to liver cells than others, though they are equally effective in destroying red blood cells. With the free base, a dog weighing 10.4 kg. died, after 0.294 gm., with fatty degeneration of the liver and areas of necrosis. Hydrazin sulphate was slightly more toxic. With phenylhydrazin, 120 mg. given to a dog weighing 5.9 kg. produced deficient liver function. There was marked anemia. At necropsy there was liver cell damage with marked hyperplasia of the spleen and bone marrow. A little fatty degeneration was found in the kidneys. Methylphenylhydrazin was less harmful both to blood and to liver. Diphenylhydrazin had no effect. Acetylphenylhydrazin, on the other hand, possessed the power of reducing the number of red blood cells, though not quite to the same degree as phenylhydrazin, but did no damage to the liver. The dog was given two injections (0.71 gm.) and became very anemic, but the liver efficiency was not lowered and the organ was normal at necropsy.

It seems, therefore, from these and similar observations that we may find other derivatives of the hydrazin series which will be more suitable to use for therapeutic purposes than phenylhydrâzin. Acetylphenylhydrazin, for instance, seems preferable because in animals it is less toxic to liver substance, while retaining the power of destroying red blood cells.

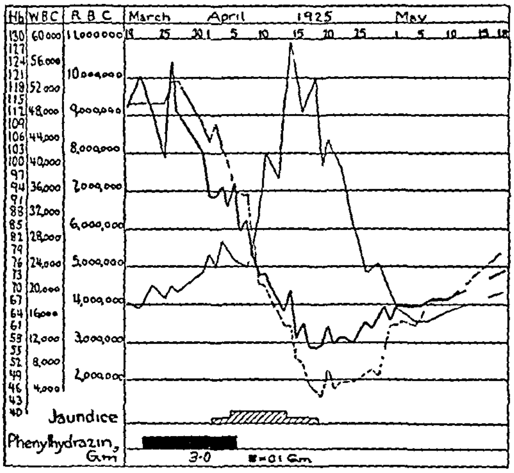

Chart 2 (Case 5).—Effect of doses of phenylhydrazin on blood count.

Whether repeated small doses of phenylhydrazin, such as were given to patients, will or will not be deleterious to the liver cannot be said yet. It is conceivable that a cirrhosis may ensue, but whether this will be any greater than that which ordinarily occurs needs further study. Levi,[6] from the study of his case which came to necropsy, decided that there is danger in the use of the drug because liver cirrhosis may be produced. He is not quite sure whether this is due to the action of phenylhydrazin directly, or occurs secondarily from the increased blood destruction. His patient was a man of 50, of nonalcoholic history, who received 7.5 gm. of phenylhydrazin during a year and a half. This was given in 0.2 gm. gelatin capsules once a day in five courses, three of 1.5 gm. each, one of 2 gm. and one of 1 gm. Each course was begun when the hemoglobin reached 110. There was jaundice and urobilinuria during these courses of the drug. The patient died of an intercurrent infection (erysipelas). The necropsy findings showed a much enlarged spleen, rich in leukocytes and with extensive deposits of blood pigment. The liver was of medium size, the surface slightly irregular, and on section was of a peculiar yellowish color. Microscopically, the interlobular connective tissue was greatly increased and infiltrated, with round cells. There were many centers of regeneration. The bone marrow was very hyperplastic, the myelocytes obliterating the normoblasts. He discussed at length the probabilities of the various factors that may cause the cirrhosis. The fact that there are cases of polycythemia with and without cirrhosis argues against the cirrhosis as a primary lesion, and he thinks that most likely the blood destruction injures the liver and that the natural course of events is only exaggerated by the artificial blood destruction produced by phenylhydrazin. He concludes by making the very fair statement that, whether the patient is left to deal with his plethora as best he can, or whether phenylhydrazin is added to assist his own resources with the chance that cirrhosis follow, is a question for each particular patient and his physician to decide. However, the latter risk is unknown and may be relatively small as compared to the risks that we know are run without treatment. Moreover, since the majority of untreated patients with polycythemia develop cirrhosis, if they escape other complications, it seems logical to conclude that their own inadequate method of blood destruction is not necessarily successful.

From these considerations and from the observations on the behavior of the leukocytes in the patients treated with phenylhydrazin, as well as in patients suffering from the toxic effects of other poisons, it is felt that the occurrence of leukocytosis in these conditions probably indicates actual destruction of tissue cells. With phenylhydrazin, in particular, the liver cells may be destroyed as well as the red blood cells.

Method of Treatment.—From these studies, it has been possible to devise a tentative plan for the treatment of patients suffering with erythremia. It is obviously most important to control the treatment by careful and frequent blood counts with especial reference to the changes in the leukocytes. This is absolutely essential when large doses of phenylhydrazin hydrochlorid are being administered.

It is safe to begin treatment by giving 0.2 gm. of phenylhydrazin a day for three or four days, and then 0.1 gm. every day until the leukocytes increase in number or the hemoglobin falls below 100 per cent. When the leukocytes rise or the hemoglobin falls, which may occur in two, three or four weeks' time, 0.1 gm. may be given every second or third day, or the drug may be stopped altogether. When the rise in leukocytes is marked, it is safest to discontinue the drug entirely. So long as the leukocytes remain high, even though this persists two weeks or more, the drug should be withheld, in spite of the fact that the red cells and hemoglobin may not fall. It is unlikely that this will happen. If the hemoglobin and red cells begin to rise or the leukocytes begin to fall, the dose should be started again or increased in frequency. Gradually the interval between doses can be lengthened, and usually 0.1 gm. once a week will suffice to keep the blood count within normal limits.

Symptoms Under Treatment.—So far, no ill effects have been noticed in these patients. Two of the patients complained of slightly disagreeable sensations after taking the capsules. In one, there was a sense of flushing and for some days slight fever. The other patient complained of a mild oppressive sensation in the neck. In two of the cases, there was slight hematuria during the administration of the drug; but as this is not an uncommon symptom of the disease and since it ceased in both patients while they were still taking the drug, it is not clear that the phenylhydrazin was the actual cause of the hematuria. Two of the patients had acute bronchitis during the treatment.

In two of the patients, the spleen increased in size at the height of the blood destruction (Cases 3 and 4) while in another (Case 5), there was a diminution in the size of the spleen. In the latter case, the liver seemed to enlarge as the spleen diminished in size. A most satisfactory result has been the reduction of the hypertension which was present in three of the patients. In Case 2, the blood pressure fell from 170/125 to 130/80; in Case 4, from 160/100 to 140/74; and in Case 5, from 167/110 to 136/80.

Changes in the Urine.—Evidently, the phenylhydrazin in some form is excreted in the urine. Soon after the drug is started, the urine, when allowed to stand, turns very dark, almost black. We do not know in what form it is eliminated. The phenolsulphonephthalein excretion in two of the patients was estimated before and during treatment, but no increase was found during the administration of the drug. Levi [6] found hematoporphyrinuria on one occasion in his case.

CONCLUSIONS

1. Phenylhydrazin hydrochlorid acted beneficially in five cases of erythremia. This was evidenced by the uniform decrease of the hemoglobin and red blood cells, a great improvement in all the symptoms and a reduction in the blood pressure of three patients with hypertension.
2. One of the early effects of the drug is a leukocytosis, noted in two cases.
3. The occurrence of a leukocytosis is a highly important index in controlling the treatment.
4. The possibility of danger, because of the toxic action of the drug on the liver, may perhaps be overcome by substituting another of the hydrazin compounds.

Orthostatic Albuminuria.—The connection between orthostatic albuminuria and a past attack of scarlatinal nephritis has been previously suggested. Bass, in 1912, gave an abstract of three papers dealing with the subject. Weiss-Eder allowed forty children with scarlet fever to kneel in a position of lordosis, with the result that twenty-three developed an albuminuria. The writer concludes that children convalescent from scarlet fever are not more disposed to nephritis than other children, and that such children, having nephritis, often show an orthostatic albuminuria, "which may be due to weak muscles." Nothman found that in twelve out of thirteen cases of scarlet fever in which at an earlier date the lordotic experiment was positive, albumin appeared later in the urine, but that in those in which lordosis did not cause albuminuria, albumin never appeared spontaneously later on. He concludes that, just as nephritis may terminate in orthostatic albuminuria, so conversely an orthostatic albuminuria may be the first sign of nephritis. Schick says that orthostatic albuminuria following scarlet fever has a good prognosis, and refers to Jehle, who examined seventeen children in various stages of scarlet fever.—Russell, J. W.: *Lancet*, Oct. 3, 1925.

Clinical Notes, Suggestions and New Instruments

A CASE OF TULAREMIA

W. L. Brown, M.D., and C. P. Brown, M.D., El Paso, Texas

A. L., a man, aged 58, a locomotive engineer, while oiling his engine preparatory to leaving El Paso at 8 p. m., Aug. 17, 1925, was bitten by an insect just above the prominence of the left cheek, three-fourths inch below and to the left of the eye. He noticed that it was an unusual bite, and thought it must have been made by a very large mosquito.

He made his run and by midnight began to have swelling in the region of the bite and pain in the glands on the corresponding side of his neck. He slept the following day. When he got up at 5 p. m., the glands were much swollen and were very tender and painful; there was considerable swelling at the site of the injury. He had no appetite and thinks he had fever at that time.

He brought his train back to El Paso that night, but the following morning he ached all over as if he had grip, was chilly, had fever, and the glands were painful. He took a cathartic, put cataplasma kaolini on the site of the injury and went to bed for his day's sleep. He awakened, sweating and chilling, during the day.

We saw him at our office on the fourth day, at which time he looked as if he had been sick a month. He was still feeling very bad and had a temperature of 102; the glands were sore, and he was having drenching sweats when he slept and all the symptoms of an acute infection. At the site of the injury there was a hard papular area one-fourth inch in diameter; it was raised, and the apex indicated that it was suppurating. On removal of the skin covering this area, it showed evidence of a necrotic core. This core did not loosen and fall out until the eighth day, when it came away leaving a cavity so clear cut that it looked as if it had been punched out. The walls of this cavity were considerably above the surface of the skin, and the surrounding area was still very hard. There was no involvement of the eye. There seemed to be no question from the beginning that the insect bite was the cause of the illness. On the third day of our care we suspected tularemia, as the clinical picture was typical.

August 29, a blood examination showed white cells, 11,500, with 75 per cent. polymorphonuclears. Typhoid, paratyphoid A, and paratyphoid B agglutinations were negative. The urine was normal. September 1, two guinea-pigs were inoculated subcutaneously, one from a swab, and the other from scrapings of the ulcer. Both pigs died, September 5, within a few hours of each other, and the postmortem examinations showed typical lesions in the spleen and the liver, as described by Francis.[1]

The liver and the spleen from these dead animals were mixed with food and given to two other guinea-pigs which were confined in the cage in which the former had died. After a week of living in this cage and eating this food, they developed no symptoms.

September 12, agglutination for tularemia was positive in a dilution of 1:320. October 2, a suppurating cervical gland was opened, and two guinea-pigs were inoculated with this pus—from which, unfortunately, no cultures or smears were made—and twenty days later they showed no signs of ill health. On the nineteenth day following the inoculation, one of the pigs gave birth to a normal baby. This experiment would suggest that the pus did not contain *Bacterium tularense*. October 3, agglutination tests were positive in a dilution of 1:2,560, as reported by the U. S. Public Health Service.

The diagnosis in this case was made clinically on account of the history of an insect bite; enlargement and pain in the glands in the drainage area within twelve hours, with all the symptoms of a serious, acute, septic condition within forty-eight hours, especially characterized by chills and drenching sweats, and rapid loss of weight. Our patient lost 16 pounds (7.3 kg.) within eight days. Also, the local lesion was entirely characteristic, a hard papule one-fourth inch at the base, much elevated, and with extreme induration, the core falling out on the eighth or tenth day, leaving a clear cut, punched out hole.

The suspension of dead bacteria for the agglutination tests was secured from the U. S. Public Health Service, Washington, D. C., by Dr. John W. Tappan, United States public health officer, El Paso, and the laboratory work was done by Dr. Willis W. Waite, El Paso.

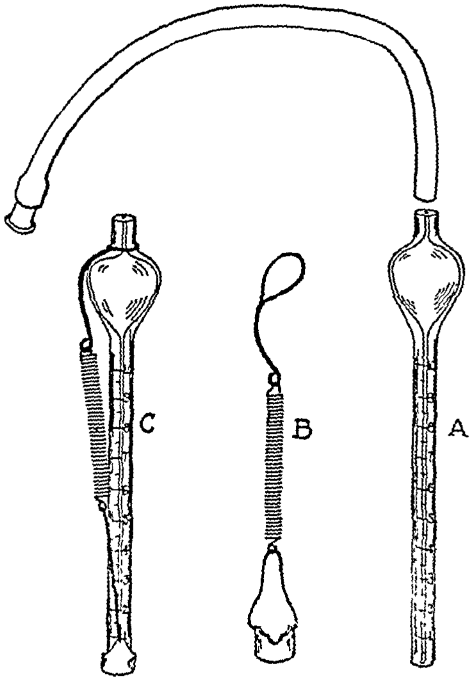
SEALING DEVICE FOR HEMATOCRIT *

C. M. Van Allen, M.D., New Haven, Conn.

An hematocrit that has proved satisfactory because of its accuracy and simplicity and the small amount of blood required has already been described.[1] Recently, the efficiency of the instrument has been improved, by the substitution of a mechanical sealing device for the rubber band originally employed for the purpose of closing the lower end of the hematocrit during centrifugalization.



Sealing device for hematocrit.

The complete apparatus in its improved form is shown in the accompanying illustration. The hematocrit (*A*) consists in a capillary bulb pipet about 10 cm. in length. The shaft, from the lower extremity to the bulb, is graduated in a scale of 100 parts, the bore beneath this scale being of uniform caliber. A rubber mouth tube is fitted above the bulb. The sealing clip (*B*) is constructed of three parts: a wire loop to fit over the bulb; a metal cup, rubber cushioned, to enclose the end of the shaft, and a coil spring to retain the clip in place (*C*). The cushion is a rubber disk, such as may be cut from a broad rubber band, and is renewed readily. This clip fits also the standard hemocytometer pipet and is of use in conveying the filled pipet from a distance to the laboratory. Directions for the use of the hematocrit will be found in the papers referred to above.

---

* From the Laboratories of the Rockefeller Institute for Medical Research, New York.

* The hematocrit and sealing clip may be obtained from Arthur H. Thomas and Company, Philadelphia.

SATURDAY, DECEMBER 26, 1925

LEAD POISONING

Within the brief period of thirteen years prior to the World War, more than 8,000 cases of plumbism with nearly 400 deaths were reported to the British Home Office as arising in the trades of the comparatively small population of Great Britain. Lead poisoning has existed from time immemorial. Students of the subject have ventured the statement that as little as 1 or 2 mg. of lead taken into the body each day is likely to lead to chronic poisoning. This represents a content of only one part of lead in 70,000,000 in the body of an adult of 70 kg. body weight. We cannot contemplate such possibilities without an appreciation of their seriousness. Guidance in combating the evil is eminently desirable.

It is therefore a fortunate circumstance that a group of investigators[1] working at the Harvard School of Public Health and the medical clinic of the Massachusetts General Hospital has been enabled to undertake a detailed study of the varied manifestations of a preventable hazard. The report of these investigators, recently made available, though reviewing much that has already been well established or clearly recognized, nevertheless serves to emphasize some of the factors—chemical, biologic, pathologic and clinical—that deserve emphasis at this time. The report makes evident anew that the route by which lead enters the organism most rapidly is the respiratory tract. Hence, the exposure to be most guarded against is the inhalation of finely divided particles. Next in danger comes the continued ingestion of lead compounds, and last of all, the possible slow cutaneous absorption in persons with tender, irritated or broken skin.

According to the Harvard studies, differences in distribution are found early in lead absorption, dependent on the route by which lead has entered the organism. Following absorption from the gastro-intestinal tract, the liver contains a relatively high concentration of lead as a result of the retention of this toxic substance, which it removes from the portal blood. From the lung or subcutaneous tissue, on the contrary, lead enters the general circulation; hence, only a small portion of it is carried directly to the liver. Once in the general circulation, the lead is distributed throughout the organism. Since the skeleton is the only tissue to retain permanently any significant amount of lead, an ever increasing percentage of the total absorbed lead comes to be stored in the bones. After absorption has ceased, this selective localization of lead becomes practically complete. While stored in such a deposit the lead is apparently harmless, since the symptoms of plumbism are noted only when lead is generally distributed throughout the organism, as a result either of recent absorption from an external source or of mobilization of a skeletal store.

On the basis of the thesis that, after absorption into the general circulation, lead is either stored in the skeleton or eliminated from the organism by excretion, the problem of treatment may be more rationally approached. Obviously, during severe intoxication it would be wise to facilitate storage of lead rather than rapid mobilization of the element, because the latter might increase the "toxic episodes." In this connection the Harvard toxicologists have reported an important analogy between the metabolism of calcium and that of lead. Various decalcifying agents have been shown to increase the lead output. Conversely, conditions favoring calcium retention tend toward a complete storage of lead in the bones. Consequently, during periods of danger it is advised to facilitate storage of lead by the ingestion of ample calcium, rather than to set the lead free. After the acute toxic manifestations have passed, elimination of lead may be accelerated by a low intake of calcium, acids and their ammonium salts, sodium bicarbonate and potassium iodid. Caution should be exercised in using these forms of treatment on patients with nephritis.

Chemical studies have indicated that the products of the reaction between secondary sodium phosphate and a lead salt are tertiary lead phosphate and acid. This lead salt is very stable at the normal hydrogen ion concentration of the body, but is sensitive to slight changes in acidity and passes into the more soluble di-lead salt readily. The marked solubility of lead and lead oxid in such body fluids as blood plasma may account for the high incidence of lead poisoning among workers exposed to lead fume and lead oxid dust. Both gastric and pancreatic juice may transform insoluble lead salts into more soluble forms and may therefore cause an increased absorption of lead compounds. Lead is probably transported in the blood stream in the form of colloidal lead phosphate, and deposited in the bone tissue as tertiary lead phosphate. Tertiary lead phosphate is sensitive to changes in acidity, particularly to variations caused by such acids as lactic; this may in part account for the fact that the concentration of lead in muscle is low and in bone tissue is high. The sensitiveness of tertiary lead phosphate to changes in hydrogen ion concentration may be an important factor in the frequent development of acute lead intoxication following acute infection or acidosis. It is generally agreed that by far the greater proportion of eliminated lead leaves the body with the feces. This is true of various other elements, such as calcium and iron. Some of them use the pathway of the bile as well as the gastro-intestinal epithelium. Small amounts of lead usually escape simultaneously through the kidneys. As one cannot readily determine whether fecal lead has actually been absorbed and reexcreted into the bowel, or merely has passed unchanged through the alimentary canal, the detection of lead in the urine is of greater clinical and diagnostic significance than the proof of its presence in the stools.

---

[1] Aub, J. C.; Fairhall, L. T.; Minot, A. S., and Reznikoff, P.: Lead Poisoning, Medicine 4: 1 (Feb.-May) 1925.

The sources of lead poisoning are manifold. Plumbism is a menace of many well recognized trades. There are, however, unsuspected byways through which lead may find its way into the body. One of these is contaminated alcoholic liquors. Instances of lead poisoning from the consumption of "moonshine" whisky evidently contaminated by the stills have been reported.[2] Among eighteen samples of liquor known to be used by saturnines, all except two showed the presence of lead. Inappropriate apparatus used in the manufacture and storage of wines and distilled liquors account for these disconcerting findings. The widespread use of containers glazed with lead compounds and the careless use of leaden or soldered containers in the preparation of home-made beverages are, therefore, matters of concern from the point of view of health.

A NEW FEATURE OF VITAMIN DEFICIENCY

Despite much investigation during the last decade as to the nature of deficiency diseases, little more has been done than to scratch the surface. Rapid additions to our knowledge, such as the spectacular discovery that pure cholesterol can be given vitamin activity through the influence of ultraviolet radiation, continue to be announced. Information that most concerns the practicing physician, namely, the extent to which minor degrees of vitamin deficiency modify human health, is still lacking, however. What relation, if any, has vitamin deficiency to resistance to infection, to fatigue, to well being? Most of the investigation of vitamins up to the present having been carried out in the laboratories of the physiologists and biochemists, the anatomic changes resulting from dietary deficiency have perhaps not yet been investigated as much as may be profitable. At least that is the inference that may be drawn from the interesting observations just reported by a pathologist, Wolbach of Harvard, on the effects of protracted deprivation of fat-soluble A vitamin.[1]

It has long been known that changes occur in the eye, the so-called xerophthalmia or keratomalacia, associated with drying, hornification and infection of the cornea, which have been considered to be characteristic of a deficiency of fat-soluble A. Wolbach and Howe find, however, that the eye changes are by no means the only anatomic effects of this deficiency, for they are only a part of a remarkable, widespread tendency for transformation of secreting and ductal columnar epithelium, or of transitional epithelium, into the heavily hornified type of epithelium normally serving for protective purposes. This metaplasia is found not only in the cornea and parocular glands, but even more extensively in the entire respiratory tract, from nose to bronchi; it is also found in the lining epithelium of the urinary passages, the salivary glands, the prostate, the uterus and oviducts, and the pancreatic ducts. Besides this tendency to keratinization there occurs a marked loss of fat, despite the presence of an abundance of fat in the animal's diet, and atrophy of glandular organs, especially the testes, spleen and salivary glands; but these atrophic changes are produced also by a deficiency of some of the other vitamins. Necropsy in a single case of deficiency of fat-soluble A in a child[2] has revealed hornification of the epithelium in the lungs, uterus, submaxillary glands, pancreatic ducts and renal pelvis, so that this effect seems to be a general one.

The process of keratinization begins in numerous foci, apparently independent of local infection or trauma, and spreads out from these, sometimes the hornified cells underlying for a time the original epithelium, which eventually is lost. Sometimes this process becomes so extensive that the hornified masses obstruct ducts, so that cysts are produced, and in the lungs bronchiectatic cavities form. A feature that is certain to arouse discussion is the resemblance at times of this proliferation of hornifying epithelium to the early stages of carcinoma formation, especially since occasionally metaplasia of columnar to stratified epithelium precedes carcinoma formation, particularly in the lungs and renal pelvis. Is it possible that a deficiency in fat-soluble A has anything to do with the formation of squamous cell carcinoma? At first glance this seems unlikely, for in general good nutrition seems to be more favorable for cancer formation than poor nutrition. But as yet we know too little about the relation of nutrition to cancer, or about the relation of vitamin content of human food to vitamin absorption and utilization, to speak with any assurance on this question. In any event, the demonstration that an absence of something in the food may cause active overgrowth and change in the character of body cells is an important episode, with stimulating possibilities for future developments.

THE CAPILLARY PERMEABILITY OF DIFFERENT ORGANS

Whether the exchange between the blood and the fluid in the lymphatic system proceeds entirely according to simple physicochemical principles was the subject of active discussion thirty years ago. There was an outspoken tendency at that period to abandon all so-called vitalistic explanations of circulatory phenomena in the body so far as current knowledge would permit. Mechanical theories became dominant. In connection with the origin of lymph,[1] it was pointed out that the forces in activity are, first, intracapillary pressure, tending to filter the plasma through the endothelial cells composing the walls of the capillaries; and, second, molecular energy in the form that gives rise to the phenomena of diffusion and osmotic pressure. By the action of this force, the flow of water from one place to another is influenced in accordance with the difference in concentration of the dissolved substances. These two forces acting everywhere control primarily the amount and composition of the lymph.

The foregoing theory, which has enjoyed a long survival of popularity, has not persisted without meeting serious obstacles. There are admitted phenomena that are difficult of explanation on the basis just propounded. The flow of lymph varies widely in different regions of the body, and there are some differences of composition. Consequently there has been a disposition to assume an added physiologic factor—something related to the boundaries between the blood and lymph streams, the cellular vessel walls. A recent writer,[2] in discussing the dilemma, points out that, desirable as it is to draw on physical and chemical forces for the explanation of fluid exchange, it is nevertheless impossible to escape the belief that the individual endothelial cells have the ability to regulate to some degree the transport of substances through their cell wall and cytoplasm. As an example, he adds that the lymph has frequently been considered a product of endothelial activity.

Under the test of experiment, Lee[2] has found anew that a definite change in the blood, such as the introduction of foreign substances, may produce unlike lymphatic responses in different regions. The lymph or tissue fluid derived from the brain capillaries does not invariably correspond with the *lymph originating* from the capillaries of the viscera under such circumstances. In other words, there seems to be a fundamental difference in the behavior of blood capillaries of different organs. In Lee's tests, the small vessels of the brain did not dilate like the visceral capillaries after histamin was given. They did not indicate the same fluid exchange with crystalloids as did the capillaries in organs drained by the lymphatic system. Furthermore, the passage of particles of India ink from the blood to the lymph vessels of the liver indicated the high degree of permeability in the blood vascular bed of that organ. Accordingly, there is something cogent in Lee's deduction, from such physiologic differences, that the capillaries in every organ are adapted particularly for the function of the organ in question. Whether this adaptation is an inherent quality of the capillary endothelium or whether it is due to influences arising in the tissue around the vessel, or both, cannot be stated. It is obvious, Lee concludes, that explanations based, even though only partly, on known physical and chemical laws are preferable to views depending on indefinite properties of cytoplasm; unfortunately, these laws do not completely suffice, and therefore an active participation of the endothelial cells must be considered.

---

UREA AS A DIURETIC

The once widely fostered belief that the intoxication of uremia is due chiefly to substances that are normally eliminated in the urine has practically been abandoned. If any chemical compound is to be held responsible, it seems more likely to be found among more harmful by-products of metabolism that accumulate in the blood. At any rate urea, the most prominent and abundant of all the ordinary urine components, has lost the reputation for pronounced toxicity with which it was formerly endowed. The body will withstand introduction of large quantities of urea without appreciable harm, and this nitrogenous catabolite is freely distributed throughout the fluids and tissues of the organism and appears to be eliminated with comparative ease. According to Hewlett[1] and his co-workers, after the ingestion of 100 gm. of urea by normal persons, the urea nitrogen of the blood can be raised to a figure comparable with that obtained in cases of chronic nephritis. When the blood urea exceeds 70 mg. per hundred cubic centimeters, symptoms of headache, dizziness and slight somnolence may occur. Whether these are due to the sudden alteration in the composition of the body fluids and tissues, or whether they are toxic effects produced by the urea itself, has not been determined.

The foregoing instances represent extremes of urea concentration in the blood. Confidence in the relative harmlessness of urea when the function of the kidneys is good rather than impaired was exhibited more than a quarter century ago when the use of the substance as a diuretic was proposed. That it can be given with impunity to patients over long periods has been demonstrated anew by Crawford and McIntosh[2] at the Hospital of the Rockefeller Institute for Medical Research. They have administered it in doses of from 30 to 60 gm. a day in cases of advanced cardiac decompensation that have not responded satisfactorily to the methods usually employed in the treatment of cardiac edema.

---

[1] Hewlett, A. W.; Gilbert, Q. O., and Wickett, A. D.: The Toxic Effects of Urea on Normal Individuals, Arch. Int. Med. **18**: 636 (Nov.) 1916.

The choice of a diuretic is rarely an easy problem. Urea is rapidly absorbed, and an increase immediately occurs in the height of the urea in the blood. The mean level of the urea in the blood is dependent on the dosage, and the relationship between them is fairly constant in any particular case. The amount of urea excreted depends on the blood urea, so that with constant urea administration a state of equilibrium is reached between the intake and the output. Crawford and McIntosh further point out that during urea diuresis the excretion of water runs more or less parallel with that of urea, so that urine volume reflects the concentration of urea in the blood. Undoubtedly, they add, the explanation of the diuresis is that the excess of urea circulating in the blood is excreted by the kidney, and during the process carries with it a considerable amount of water. With continuous administration, the daily urine volume was maintained at an almost constant level in their patients. The response after administration was rapid, but the effect passed off in a short time, unless the dose was repeated. In contrast with various renal vasodilator drugs and kidney cell irritants, urea seems to function well in promoting a normal water balance in the body. The New York clinicians believe that it deserves a greater popularity.

Current Comment

IS THE PITUITARY ESSENTIAL TO LIFE?

Information regarding the actual functions of the pituitary gland is singularly conflicting. In few domains of physiology are equally contradictory data supplied by investigators of scientific repute.[3] Contrary to the earlier students of the subject, Paulesco[4] maintained the thesis that the hypophysis is necessary to life. His conclusions were based on the outcome of surgical extirpation of the pituitary and were subsequently supported by the independent observations of a number of experienced investigators, including Cushing and his co-workers in this country. It might be assumed that the failures to produce fatal conditions through hypophysectomy have been due to incomplete operations; yet postmortem examinations have left no warrant for such a conclusion. An explanation of the divergent results appears to have been furnished by Dandy and Reichert[5] of the department of surgery at the Johns Hopkins Hospital. They point out that, as an organ well secluded at the base of the brain and skull and attached to both at the central point, the hypophysis has offered great difficulties of operative approach preparatory to its extirpation. It seems likely, therefore, that for the seemingly paradoxical results now on record the operative procedure itself must be held responsible. Cerebral trauma is not easily averted. Lassitude, drowsiness and even coma, as well as convulsions, are occasional complications of human intracranial operations; and it has been precisely such symptoms that have attended the experimental hypophysectomies which have had a fatal outcome. Dandy and Reichert have perfected an operative technic that permits the safe removal of the hypophysis in dogs, the species about which the controversies have revolved. With their procedure the Baltimore surgeons have, as they express it, found no evidence to support, and every evidence to refute, the assumption that the hypophysis is essential to life, or that the group of symptoms described by others as preceding death in hypophysectomized animals is of hypophysial origin.

BACTERIOPHAGE NEWS

There is a fascinating aspect to the conception that bacteria are subject to enemies within their own camp. Mankind has been industrious in devising ways of destroying the harmful micro-organism by a great variety of devices. Chemical as well as physical agents have been requisitioned in this bitter warfare; and when there has been no adequate kind of ammunition devised or available, defensive barriers have been erected. Antisepsis has vied with asepsis as a protective device. There can be no cessation of activities, for the menace is ever present and seizes every advantage of laxity on the part of the armies of preventive medicine. Lack of preparedness invites momentary human disaster. In the midst of this tension has come the news of the bacteriophage, the reputed discovery of a filtrable, ultramicroscopic virus, parasitizing on and destroying actively growing, susceptible bacteria. Such a prospect of unsuspected potent help has been hailed with interest and enthusiasm not only by the scientist but also by the layman. Sinclair Lewis gave it publicity as a leading theme in the much discussed novel "Arrowsmith." It was d'Herelle's idea that there is only a single bacteriophage, common to man and animals, capable by adaptation of acquiring a virulence toward all bacterial species.[6] This view of the unity of the lytic principle has been considerably debated. Obviously the determination of whether there is a multiplicity of bacteriophagic agents, each of which is more or less specific for definite microbes, is of great importance in attempts to employ the bacteriophage in the warfare against infection. At the Rockefeller Institute for Medical Research, Bronfenbrenner and Korb[7] have lately observed persistent differences in the individual resistance of lytic filtrates active against different micro-organisms in ways that lead them to favor the conception of the multiplicity of bacteriophages. This dissipates, for the moment, at least, the hope of a single universal panacea for those infected with bacteria.

Association News

THE DALLAS SESSION

Special Exhibit by the Section on Dermatology and Syphilology

In connection with the Dallas Session, the Section on Dermatology and Syphilology will again conduct an exhibit. The committee in charge is composed of E. D. Crutchfield, Galveston, Texas; Fred D. Weidman, Philadelphia, and I. L. McGlasson, San Antonio, Texas, chairman. According to the plans of the committee, the exhibit will not be miscellaneous but planned to illustrate the various phases of cancer, in all stages. It is intended to make it of interest to the profession at large as well as to the members of the section.

Circular letters explaining the exhibit, with application blanks, will be mailed to those who registered in the Section on Dermatology and Syphilology during any of the last five sessions. Others who desire this literature may obtain it by communicating with I. L. McGlasson, City National Bank Building, San Antonio, Texas. All applications must be sent to Dr. McGlasson by February 1.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Personal.—Dr. Randolph F. Hunter and Dr. Harold W. Comfort have taken up their duties as chief surgeon and associate physician, respectively, at the Scotia Hospital, Scotia, succeeding Drs. Charles C. Cottrell and Frank K. Haight, both of whom recently resigned to engage in private practice.

Resolution About Anesthetists.—The Community Hospital, Long Beach, recently passed the following resolution regarding anesthetists:

> WHEREAS, The California Medical Association has declared that the administration of anesthesia is the practice of medicine.
>
> WHEREAS, The attorney-general of the state of California has ruled that the giving of an anesthetic is the practice of medicine.
>
> WHEREAS, The board of medical examiners of the state of California has ruled that the giving of an anesthetic is the practice of medicine.
>
> WHEREAS, It is against the spirit of the law, against the ethics of medicine, and against the ruling of a large majority of accredited hospitals for nurses or any one else not legally qualified to practice medicine to give an anesthetic in California.
>
> WHEREAS, The superior courts of two states of the United States have already handed down decisions fixing the liability for damages against hospitals in which nurses have administered anesthetics at the time of the death of the patient while under influence of the anesthetic, judgments against the hospital to the extent of $10,000 for damages in one case, and $150,000 in another case having been obtained.
>
> WHEREAS, The Community Hospital of Long Beach intends to comply with the spirit of the laws of the state of California, the code of ethics of the American Medical Association, and all the requirements for an accredited hospital; therefore, be it
>
> *Resolved,* That the administration of general and local anesthesias in the Community Hospital of Long Beach be limited and restricted exclusively to Doctors of Medicine (M.D.'s) legally qualified to practice medicine and surgery in the state of California.

FLORIDA

En Route to Florida.—The secretary of the California State Board of Medical Examiners notified the Florida Board of Examiners, November 10, that one A. L. Oxford, who had in some way obtained the California license to practice medicine of Dr. Fletcher A. Butler, deceased, was on his way to Florida. A complaint was filed against Oxford in Los Angeles, November 7, charging violation of the medical practice act; he is also said to have been arrested in 1924 for petty larceny.

GEORGIA

Pleadings in Suit for Fees.—The Georgia Court of Appeals has affirmed a judgment by which Dr. D. Granville Humphreys of Fernandina, Fla., was awarded $310, against J. H. Becker of St. Mary's, Georgia, for services rendered a third person at Becker's request. Liability was denied by Becker in the court of appeals because Humphreys had not alleged in his pleadings that he had been licensed to practice in Georgia. The court held that in an action for the value of professional services, it is sufficient for a physician to allege that he is a physician, that he was employed as such, that he rendered the services alleged, and that the reasonable value of such services was the amount sued for. The court held further that the law does not raise an implied promise by a third person to pay for professional services rendered a patient at his request, but that a physician must prove an understanding between himself and the third person that the third person, and not the patient, would pay.

IDAHO

Personal.—The governor has appointed Dr. Ralph M. Fouch, American Falls, medical adviser of the state department of public welfare, to succeed Dr. Frank W. Almond, resigned.

ILLINOIS

Scarlet Fever Increasing.—The prevalence of scarlet fever in the state is 25 per cent. in excess of what it was this time last year, and, according to the state department of health, it is steadily increasing; 414 cases were reported last week, whereas 109 were reported the first week in October. The department says that the greatest monthly prevalence of scarlet fever in the state habitually occurs in January.

Chicago

Medical History Club.—The medical history club, recently organized at the University of Illinois College of Medicine, was addressed by Mr. Christian Bay of the John Crerar Library, November 4, on "Observations of a Medical Librarian Abroad"; by Arthur H. Daniels, Ph.D., dean of the Graduate School, University of Illinois, December 2, on "The Philosophy of Spinoza," and by Dr. Morris Fishbein, December 16, on "Eclecticism." The next lecture will be by Dr. Basil C. H. Harvey of the University of Chicago, on "Vesalius."

Dr. Falls Appointed Professor at Illinois.—Dr. Frederick H. Falls, Iowa City, has accepted the appointment of professor and head of the department of obstetrics and gynecology at the University of Illinois College of Medicine, Chicago. Dr. Falls, who formerly was an instructor in that department at Illinois, has since 1921 been head of the department of obstetrics and gynecology at the State University of Iowa College of Medicine, Iowa City; he is a graduate of the University of Chicago and Rush Medical College, and has a master's degree from the University of Illinois. ——The announcement in THE JOURNAL, December 12, of the appointment of Dr. Carl A. Hedblom should have been as professor and head of the department of surgery at the University of Illinois.

Rawson Laboratories Dedicated.—The new Rawson Laboratories connected with Rush Medical College were dedicated with appropriate ceremonies, December 18. The building is five stories high, of steel construction, joined on one side with the Presbyterian Hospital and on the other with the Senn Memorial building. On the first floor are administrative offices and library built for more than 25,000 volumes; the second, third and fourth floors are for classrooms, examining rooms, reception rooms and special laboratories. Surgery occupies the entire fourth floor, and the Norman Bridge pathologic laboratories the fifth floor. The Central Free Dispensary, which last year treated more than 100,000 persons, will be in this building and the Senn Memorial building. There is a children's play room for mothers who, in seeking treatment, bring their children, and a play director in charge. There are small treatment rooms throughout the building, two operating rooms on the fourth floor for minor operations, and various small laboratories for medical research for advanced students. The laboratories have the latest improvements. The building generally is of the most modern type.

---

[7] Bronfenbrenner, J. J., and Korb, C.: Studies on the Bacteriophage of d'Herelle, IV, Concerning the Oneness of the Bacteriophage, J. Exper. Med. **42**: 821 (Dec.) 1925.

INDIANA

[illegible] Board of Health.—According to the [illegible] or-elect Duvall has announced the [illegible] E. Padgett to be president of the board of health, and of Dr. William E. Mendenhall, Dr. Arthur E. Guedel and Dr. Frederick E. Jackson as members.

Personal.—Dr. Charles L. Cabalzer, Indianapolis, has been elected president of the staff of the Methodist Hospital for the coming year.——Dr. William A. Buchanan has been appointed for the third time commissioner of health of Hammond.——Dr. Urval C. Ambrose has been appointed a member of the board of directors of the Indiana Christian Hospital, Indianapolis.——Mayor-elect Tinkham of Gary has announced the appointment of Dr. William M. Bigger as president of the board of health, and Dr. William A. Buchanan as secretary.

Annual Report of State Board of Health.—The birth rate in Indiana in 1924 was the highest recorded in ten years (22.4); the death rate from diphtheria, scarlet fever, tuberculosis and maternal causes, and the infant mortality rate were the lowest on record. There were 534 deaths in the state from automobile accidents, as against 362 in 1922, and this cause now leads all other accidental causes of deaths. Among 208 brains of dogs and other domestic animals examined for rabies, seventy-six were positive, and ninety-two persons were given the Pasteur antirabic treatment in the laboratory. The division of school hygiene made sanitary surveys of 139 school buildings, condemning thirty-eight, practically all of which were old one-room structures; the division also approved plans for ninety-three new school buildings and specifications for remodeling seventy-seven old school buildings. Health films were shown to more than 23,000 people by the division of child hygiene, which also held 1,938 mothers' classes, with an attendance of about 48,000.

KANSAS

Personal.—Dr. Fred C. Cave, Grainfield, who has been appointed full-time health officer for Ellis County, assumed his duties, November 1.——Dr. Sydney P. Loomis, formerly of Lost Springs, has purchased the Virginia Hotel at Herington, which he will convert into a hospital.

LOUISIANA

Hospital News.—The French Hospital, New Orleans, which for sixty years has been maintained by a society of persons of French descent, is being remodeled from a forty-five bed hospital to a ninety-bed hospital and will be at the service of the entire city. The institution is owned by the Société Française de Bienfaisance et Assistance Mutuelle.

Gifts to Hospitals.—Mr. Luca Vaccaro has given $10,000 to the Southern Baptist Hospital, New Orleans, to equip the roentgen-ray department. The hospital will be formally opened in January.——Mrs. John Dibert has given to the Eye, Ear, Nose and Throat Hospital, New Orleans, another gift of $50,000, making her total donation to that institution $135,000.

Society News.—The Orleans Parish Medical Society, New Orleans, has unanimously recommended Mr. F. W. Evans, vice chairman of the board of Charity Hospital, for the award of the annual *Times-Picayune* cup given to the citizen doing the greatest work of outstanding character.——The annual dinner of the Orleans Parish Medical Society was held, December 12, following the annual election.

Professor Castellani En Route to New Orleans.—Prof. Aldo Castellani sailed from London, December 16, for New York en route to New Orleans to take up his duties as professor and head of the department of tropical diseases at Tulane University of Louisiana School of Medicine. According to Dean Bass, new office and laboratory equipment is now being installed in the Hutchinson Memorial building so that Professor Castellani can take up the organization of his department on arrival. It will be essentially a research department. It will provide service for the Charity Hospital, and give instruction to the undergraduate classes. Although not formally enrolled in the faculty of the graduate school, Professor Castellani will give graduate instruction (The Journal, November 7, p. 1494).

MARYLAND

Joint Meeting on Cancer.—A joint meeting of the Maryland Cancer Committee, the Baltimore City Medical Society and the Baltimore City Dental Society was held, December 18, at Osler Hall, Baltimore, to discuss "Research Work on Cancer in This Country and Abroad." Dr. George A. Soper, managing director, American Society for the Control of Cancer, who has just returned from Europe, discussed the work of Gye and Barnard; Dr. William H. Woglom, associate professor of cancer research, Columbia University College of Physicians and Surgeons, New York, discussed the experimental side of cancer in relation to diagnosis and treatment, and Dr. William H. Welch, director, Johns Hopkins School of Hygiene and Public Health, discussed both subjects.

Anniversary of Medical School.—The one hundred and eighteenth anniversary of the founding of the School of Medicine of the University of Maryland was commemorated, December 17, by a banquet at the Hotel Emerson, which members of the faculty and alumni from New York, Philadelphia, Baltimore, Washington and other cities attended. Chartered by the legislature, Dec. 7, 1807, as the College of Medicine of Maryland, it was the first unit of the University of Maryland, the sixth institution of collegiate standing to be founded in Maryland, and the third in Baltimore, and also the fifth medical school to be established in this country. Dr. John B. Davidge, who settled in Baltimore in 1796, the year in which the city received its charter, was the founder, and Dr. James Cocke, a native of Virginia, and Dr. John Shaw of Annapolis were his associates. At the banquet, December 17, Dr. Arthur M. Shipley, professor of surgery, was toastmaster, and among the speakers were Dr. William S. Love, president, alumni association; Dr. Maurice C. Pincoffs, professor of medicine, and Dr. James M. H. Rowland, dean of the medical department.

MASSACHUSETTS

Personal.—George E. Vincent, Ph.D., president of the Rockefeller Foundation, New York, will deliver an address at the celebration of the fiftieth anniversary of the Boston Medical Library, Jan. 19, 1926.

Hospital News.—The Florence Crittenden League of Compassion has dedicated a new maternity hospital and home on the site of the old Peter Faneuil homestead, Oak Square, Brighton. The league is conducting a campaign to raise $150,000 to carry on this work.

Society News.—Dr. Harry C. Solomon, Boston, addressed the North Shore Medical Fraternity at Lynn, November 24, on "Epilepsy: Its Various Forms and Treatment."——Prof. Vittorio Putti addressed the Harvard Medical Society at the Peter Bent Brigham Hospital, Boston, November 30, on "History of the University of Bologna."

MICHIGAN

Diphtheria Immunization at Niles.—Local physicians and nurses cooperated with the health officer of Niles during the last four weeks to administer toxin-antitoxin to the 1,200 school children to immunize them against diphtheria. According to the Niles *Star,* this work was completed before there had been any serious outbreak of diphtheria this year. This was part of the program of the state board of health to eradicate diphtheria from the state. The physicians donated their services for this work.

Society News.—Dr. John Shelton Horsley, Richmond, Va., addressed the Wayne County Medical Society, Detroit, December 21, on "Biologic Principles Underlying Gastric Surgery."——Dr. Herman B. Van Wyck of the University of Toronto Faculty of Medicine addressed the Bay County Medical Society at Bay City, recently, on "Toxemias of Pregnancy."——The Alpena County Medical Society put on a program at Bay City recently in return for a program presented by local members at Alpena last May.——Dr. Hugh T. Patrick, Chicago, emeritus professor of neurology, Northwestern University Medical School, addressed the annual meeting of the Kent County Medical Society, Grand Rapids, December 16, on "Some Phases of Psychanalysis."

MINNESOTA

Society News.—Dr. David [illegible] ected president of the Minnesota [illegible] and Otolaryngology, and Dr. John H. Morse, secretary-treasurer.

Outbreak of Poliomyelitis.—At the annual meeting of the Minnesota State Sanitary Convention, St. Paul, November 5-6, Dr. Orianna McDaniel, director of the division of preventable diseases, state department of health, stated that there had been ninety-one deaths so far in the outbreak of poliomyelitis in the state since June 1, and that cases had been reported from eighty-one of the eighty-seven counties.

MISSOURI

The Adcox Confession (continued).—Adcox compares the "opening up" of Connecticut to "bringing in" a gusher in an oil field. He says in the St. Louis *Star*, that he knew nothing about conditions in Connecticut, heretofore, but he decided to tap the field with two unusually dumb men, who had $1,500 each to pay for a license. Adcox attempted in other places to get licenses for these boys, but they were so stupid that both failed to get by after he had things fixed. He called them to his home and offered to take them to Connecticut, provided they paid expenses. On arrival at the Guarde Hotel, New Haven, Adcox warned his "dumb-bells" to stay in their rooms and not talk to anybody, then went to the lobby and met the "famous fixer" who had opened up Arkansas. "Famous fixer" forbade Adcox to work in Connecticut, but the next morning, Adcox and his "dumb-bells" were the first to arrive at the examination room. Adcox, sitting between the two, wrote the examination himself and passed answers, fore and aft, for practically all the questions. "Famous fixer" and his delegation obtained the questions to be asked the next day and worked all night writing up their papers. All but one of "famous fixer's" clients passed the examination, and he was so illiterate that the board could not read his papers. Adcox's "dumb-bells" passed, but he failed, having been so busy helping others and finding out what was going on. Before the party broke up, "famous fixer" warned Adcox that although he got by this time in Connecticut, he had seen to it that he would not be on deck the next trip; he told the truth, for shortly after Adcox returned to St. Louis, "we were informed" that the diplomas of the St. Louis school would no longer be recognized in Connecticut. Adcox had at that time fifteen prospects who wanted to make the next trip. The author takes time out here to say that in all the history of medicine or of state government there has never been anything as rotten as the scandal in Connecticut. There were no requirements or restrictions, and any person willing to pay could obtain a license. The type of person that took advantage of the offer was the ignorant immigrant who knew little English and the lowest of laborers; men who had driven dump carts in January were administering anesthetics and operating for appendicitis in February; scores of murders were committed in the name of science, he says, and were covered up by phraseology in death certificates. Men too ignorant to be called quacks, who would not be tolerated in any other state, found a haven in Connecticut, and they organized, and became a potent political power. It was this, Adcox says, which he saw with his own eyes, that brought him to realize the seriousness of his offenses and caused him to determine to end his career; not yet, however, for he made plans to defeat the "famous fixer" by sending him prospects who would purchase diplomas from his institution. With Connecticut refusing now to admit applicants from the St. Louis school, Adcox sent his "graduates" to Kansas City to graduate again. "Famous fixer" not only controlled the situation in Connecticut but actually set the dates for the state board examinations; he brought with him to the Guarde Hotel, New Haven, blank diplomas for the easterners who had not gone west for "commencement" and for such unexpected applicants as put in an appearance. He failed once to obtain the questions in advance, so he called his "applicants" together and told them to go slow and he would get the questions at noon. He not only kept his word but had the meeting of the board adjourned until the next morning and devoted the afternoon and night to preparing examination papers.

Ralph Voigt went to Connecticut on one trip for Adcox, taking several "young men." He arrived too late for the examination, but a member of the board took the whole delegation to a hotel and gave oral examinations; one of this bunch, Adcox says, now has a large practice in Richmond as an eye specialist. On his numerous visits, Adcox saw matters steadily growing worse in Connecticut. Hospitals were being operated by quacks, every known "ism" was practiced, and quacks were selling their whisky prescriptions for $3 apiece. He saw now that the diploma mill had grown too big to control and that it must soon fall by its own weight. He returned to St. Louis from Connecticut, and resolved to quit the business. Before long, however, a young man who had been his neighbor for several weeks came to his home with his throat swathed in bandages. While Adcox was treating him for tonsillitis, he indicated that he had always wanted to be a doctor but had never had the chance; here, then, was another prospect, so Adcox offered to make "Harry Thompson" a doctor.

NEW JERSEY

Hospital News.—The new $1,000,000 Englewood Hospital, paid for wholly by popular subscription, was dedicated, November 27; officials and residents of twenty-two communities in New Jersey's Northern Valley attended the ceremony.

Society News.—Dr. Arthur C. Morgan, Philadelphia, conducted a bedside clinic before the Atlantic County Medical Society, November 15, at the City Hospital, and addressed the society on "Internal Medicine."——Dr. Livingston Farrand, president of Cornell University, Ithaca, N. Y., addressed the Essex County Medical Society at Newark, December 10, on "The Responsibilities of the Medical Profession to the Community."

NEW YORK CITY

Dr. Wood to Investigate Cancer Research.—Dr. Francis Carter Wood, vice president of the American Society for the Control of Cancer, sailed, December 9, according to press reports, for Europe to investigate the various recent reports on cancer research in England, and on his return will make an official report of his investigation.

Medical Diploma Stolen.—Dr. James J. Short, 110 West Fifty-Fifth Street, writes that a news item in The Journal, November 7, prompted him to report that about a year ago his medical diploma disappeared as the result of a robbery which took place while he was making professional calls. Dr. Short graduated from the University of Buffalo Department of Medicine in 1918.

Another Convalescent Home.—The family of the late J. Kennedy Tod has given his estate at Oyster Bay to the Columbia-Presbyterian Medical Center for a convalescent home for patients. The property includes two small islands and a peninsula of 117 acres extending into Long Island Sound; also permanent buildings and a long sandy beach suitable for salt water bathing.

Society News.—Dr. Wendell C. Phillips, president-elect of the American Medical Association, addressed the First District Dental Society at the Hotel Pennsylvania, December 3.——Dr. J. L. Amster addressed the Bronx Surgical Society, November 25, on "Postoperative Fecal Fistual Communicating with Ovarian Dermoid," and Dr. Benjamin Sherwin on "The Treatment of Acute Peritonitis."——Dr. Philip Liebling addressed the Bronx Gynecological and Obstetrical Society, November 30, on "Purpura Hemorrhagica."——The twentieth annual meeting of the Woman's Medical Society at New York will be held at the Hotel McAlpin, March 29, 1926.——Dr. S. Adolphus Knopf addressed the Medical Association of the Greater City of New York, December 21, at the New York Academy of Medicine on "Birth Control; Sanitary, Medical and Moral Aspects."——Dr. Thomas J. Harris addressed the New York Academy of Medicine in a program arranged in cooperation with the Section of Laryngology and Rhinology, December 17, on "End-Results of Tonsillectomy, with Especial Reference to the Legal Responsibility."——The Riverside Medical Society gave a dinner, December 15, at the Hotel Majestic in honor of Dr. Lewis G. Cole, who addressed the society on "Gastric Motor Phenomena," illustrated with motion pictures.——Dr. Emilius C. Dudley, emeritus professor of gynecology, Northwestern University School of Medicine, Chicago, addressed the Bay Ridge Medical Society, December 8.——Dr. Edward A. Strecker, Philadelphia, addressed the Medical Society of the County of New York, December 28, on "The Psychoneuroses with Particular Reference to Their Management."——The Yorkville Medical Society conducted a symposium on "Blindness Due to Sinus Disease," December 21, arranged by the otolaryngological department of Beth Israel Hospital, and were addressed by Dr. Ralph Almour on "The Ear as a Diagnostic Aid in Syphilis," and by Dr. Mervin C. Myerson on "Medical Bronchoscopy."

OHIO

Dr. Lavender Appointed Health Officer.—Dr. De Witt C. Lavender has been appointed health commissioner of Mansfield and Richland County to succeed Dr. William De Kleine, resigned, who will go to Fargo, N. D., to take charge of the American Child Demonstration there. Dr. Lavender heretofore was the deputy health commissioner.

Course in Plastic Surgery.—For the first time in this country since the World War, a course in plastic facial surgery was given this month at the University of Cincinnati College of Medicine, under the direction of the departments of anatomy and otolaryngology; the instructors were Dr. Oscar V. Batson, professor of anatomy, and Dr. Samuel Iglauer, professor of laryngology, assisted by Dr. Jacques Maliniak.

Professor Mathews on Leave.—Albert P. Mathews, Ph.D., professor of biochemistry, University of Cincinnati College of Medicine, Cincinnati, is in England on sabbatical leave, working with Prof. Edward C. Baly of the department of physical chemistry, and with Professor Ramsden of the department of physiology, at the University of Liverpool; he will also be at Oxford a short time to visit Professor Halliburton in London, and spend several months on the continent, and next June he will attend the celebration of the five hundreth anniversary of the University of Louvain.

Personal.—Dr. John H. Baird, formerly with the Veterans' Hospital in the Bronx, New York, has been detailed as clinical director of the Veterans' Bureau Hospital No. 97, at Camp Sherman, near Chillicothe.——Dr. Perry I. Tussing was elected president of the Allen County Academy of Medicine, Lima, November 17, at which time he addressed the academy on "Diseases of the Heart."——Dr. Robert C. Longfellow, Toledo, is at present house physician for American and English-speaking tourists at the Khedivial Hotel, Cairo, Egypt; he will return next spring.——Dr. M. Murray Levine has resigned from the staff of the Cleveland State Hospital, Cleveland, to engage in private practice in that city.——Dr. Trent A. B. Denison has resigned as superintendent of Lakeside Hospital, Cleveland, to engage in private practice.——Dr. William J. M. Scott, instructor in surgery, Western Reserve University School of Medicine, Cleveland, is leaving to accept the position of assistant professor of surgery in the new Rochester Medical School, Rochester, N. Y., Jan. 1, 1926.——Dr. Emile Holman, assistant professor of surgery, Western Reserve University School of Medicine, is leaving to accept the position of associate professor of surgery at Stanford University, California, Jan. 1, 1926.——Dr. James M. Snider, Marysville, has been appointed a member of the Union County Board of Pension Examiners, succeeding the late Dr. Lutrelle Henderson.——Dr. John DeForest Smith has been reelected president of the Horticultural Society of Dayton.——Dr. Ralph W. Holmes, Chillicothe, has been elected president of the Ross County Academy of Medicine.——Dr. Aaron F. Basinger has been elected president of the medical staff of the City Hospital, Lima.

OREGON

License Revoked.—The state board of medical examiners reports that the reciprocity license of Dr. Wilbur W. Illsley, Hermiston, Ore., was revoked at a meeting of the board, November 12; Dr. Illsley is still licensed to practice osteopathy in Oregon.

PENNSYLVANIA

Society News.—Dr. William D. Stroud of the Graduate School of Medicine, University of Pennsylvania, Philadelphia, addressed the Berks County Medical Society at the November meeting on "Prognosis in Heart Disease."——Dr. Alexander H. Colwell addressed the Fayette County Medical Society at Union Town, November 5, on "The Treatment of Emergencies in Heart Practice."——Dr. Thomas G. Simonton, associate professor of medicine, University of Pittsburgh School of Medicine, and Dr. Harold A. Miller, professor of obstetrics, University of Pittsburgh School of Medicine, addressed the Mercer County Medical Society recently on "Referred Pain in Pneumonia" and "Pyelitis in Pregnancy," respectively.

Pittsburgh Skin and Cancer Foundation.—In the annual report of this foundation, President Judge Reed shows that the attendance in its second year has doubled; that 557 new cases were received and 301 clinics held; of the new cases 410 were in the new skin department, ninety-three in the cancer department, of which sixteen were referred to private physicians, twenty-two were improved, two died and fifty-three are still under treatment. A department of gastro-enterology has been established under the direction of Dr. Herbert L. Jones, and a study is being made to determine any relation that may exist between gastro-intestinal and dermatologic conditions. The treatment rooms and office are at 1901 Fifth Avenue.

Philadelphia

Personal.—Dr. Edmund B. Piper has been appointed on the gynecologic and obstetric staff of the Philadelphia General Hospital to fill the vacancy caused by the death of Dr. John Cooke Hirst.

Society News.—Dr. James F. Donnelly has been elected president of the Philadelphia Clinical Association; Drs. Ernest G. Maier and Samuel P. Gerhard, vice presidents; Dr. William H. Thomas, treasurer, and Dr. Louis R. Wiley, secretary.

Biologic Abstracts.—The Rockefeller Foundation has given $350,000 to establish a biologic abstract service in Philadelphia covering the whole field of pure and applied botany and zoology. *Botanical Abstracts, Abstracts in Bacteriology* and the abstracting service of several other journals will be merged with the new service. According to the *Atlantic Medical Journal*, about 35,000 abstracts will be published annually, including papers prepared through the collaboration of biologists. The service will be conducted under the auspices of the Union of Biologic Societies of America, with headquarters at the University of Pennsylvania. The monthly journal will be known as *Biological Abstracts.* Jacob R. Schramm, Ph.D., of Cornell University, Ithaca, N. Y., has been made editor in chief and John A. Detlefsen, Sc.D., formerly of the University of Illinois and the Wistar Institute of the University of Pennsylvania, associate editor in the field of animal biology.

RHODE ISLAND

Society News.—Dr. Wilfred Pickles addressed the Providence Medical Association recently on "Sacral Anesthesia," and Dr. Elliot A. Shaw on "Some Problems Presented by Patients with Jaundice." Dr. Robert M. Lord addressed the association, November 2, on "A Report on Fifty Cases of Pyelitis in Children."

TENNESSEE

Tri-State Association Meeting.—The forty-second annual meeting of the Tri-State Medical Association will be in Memphis, Jan. 26-28, 1926, at the Hotel Peabody. This organization has held annual meetings ever since its founding in 1883, except in 1917 and 1918; last year the association honored Dr. Henry C. Dunavant of Osceola, Ark., the surviving member of the committee which wrote the constitution in 1883. Five members from each of the three states have been selected to present papers at this meeting in addition to other speakers, among whom will be Dr. Martin H. Fischer, professor of physiology, University of Cincinnati School of Medicine; Dr. Rudolph Matas, professor of general and clinical surgery, Tulane University of Louisiana School of Medicine; Dr. Thomas R. Brown, professor of clinical medicine, Johns Hopkins University Medical Department; Dr. Julius H. Hess, professor and head of the division of pediatrics, University of Illinois College of Medicine, and Dr. Bethuel B. Vincent Lyon, Philadelphia.

TEXAS

Publicity in Common.—The Dallas County Medical Society, Dallas, recently passed the following resolution:

> *Resolved,* That in appreciation of the scientific standards maintained by the dental profession generally, and out of the high regard that the Dallas County Medical Society has for the Dallas Dental Society, we extend an invitation to have such publicity committee as may exist, or may be appointed by their president, meet with a like committee of our own, to discuss publicity in which the two professions have a common interest.

Society News.—Dr. Charles S. Hale, Cisco, has been elected president of the Eastland County Medical Society.——Dr. Ewin P. Hall, Fort Worth, addressed the Tarrant County Medical Society, recently, on "The Management of a Case of Obstetrics in the Home."—Dr. Louis K. Patton, Amarillo, addressed the Panhandle District Medical Society at Clarendon, recently, on "Mercurochrome Intravenously," and Dr. Robert B. Giles, Dallas, on "The Significance of Heart Murmurs."

WASHINGTON

Society News.—Dr. Alfred H. Winkel recently addressed the Seattle Academy of Medicine on "Thoracoplasty."——The King County Medical Society, Seattle, gave a complimentary get-together dinner at the Olympic Hotel, December 14; all members who read a prepared speech and those talking more than ten minutes were fined $25; there will be no meeting of the medical section of the society, December 21, on account of the holidays.

Cult Bills.—The Public Health League of Washington notes in the *Messenger* that the cults have introduced bills in the present legislature which would provide a punishment of five years in prison for any one who gives or permits to be given any narcotic drug to any person under 21 years of age;

another bill would open up the hospitals of the state to chiropractors, sanipractors and other cults, and another would require physicians to write prescriptions in English and tell patients whenever there is a narcotic included.

GENERAL

Society News.—At the eleventh annual meeting of the Radiological Society of North America, Cleveland, December 7-11, Dr. Manly J. Sandborn, Appleton, Wis., was installed as president; Dr. Edward W. Rowe, Lincoln, Neb., made president-elect; Drs. Bertram C. Cushway, Chicago, Wesley H. Wallace, Brooklyn, and Raymond G. Taylor, Los Angeles, vice presidents, and Dr. Robert J. May, 5005 Euclid Avenue, Cleveland, secretary-treasurer.

Health Contest of Women's Clubs.—The General Federation of Women's Clubs is offering a prize to the state which shows the greatest percentage of clubs that participate in its program of health "surveys," by which the federation aims to secure a cooperative study by groups of the health laws and practices in communities. The federation is being aided in this work by the Metropolitan Life Insurance Company, the American Child Health Association and the American Public Health Association.

Resolution on Alcoholic Liquors.—The National Woman's Christian Temperance Union passed a resolution at the convention in Detroit in November to the effect that the best way to discourage the therapeutic use of alcohol and to relieve pharmacists of their present position of having to handle alcoholic liquors to fill prescriptions of physicians would be to make the sale and prescription of alcoholic beverages as medicine unlawful. The resolution commends the legislature of those states which have passed laws forbidding the sale and prescriptions of alcoholic beverages as medicine.

National Board of Medical Examiners.—There will be examinations held by the board in Parts I and II, February 10-12, in all Class A medical schools desirous of holding the examination and having a sufficient number of candidates, except in large cities, where they will be held in only one school. Candidates should notify the board's office, 1600 Walnut Street, Philadelphia, promptly; those not registered with the board sending formal applications not later than January 15. Examinations in Part III have been scheduled for Chicago in December; St. Louis, December 14-17, and New York City, Jan. 4-7, 1926.

Tax Reduction Bill Passes House.—With an amendment to reduce to the prewar rate the annual tax on physicians under the Harrison Narcotic Law, the federal tax reduction bill passed the House of Representatives, December 19. The amendment fixes the annual license fee of physicians under the narcotic law at one dollar instead of three, which has been the fee since the war period. The amendment was accepted unanimously in the House, and it is expected that the Senate will promptly accept it. Although the Secretary of the Treasury has never affirmatively approved of this tax reduction, it is known that the treasury department will not interpose objections to this amendment. The program of the administration leaders is to have the entire tax legislation disposed of in the Senate by March 1, 1926, so that the reductions will be effective March 15, when income tax returns must be filed. Since the House Ways and Means Committee held hearings on all the essential portions of the measure, the Senate Committee on Finance plans not to hold hearings on the tax bill, as such hearings would delay action. The reasons for the reduction of the narcotic tax on physicians were fully presented to the House Ways and Means Committee by Dr. Charles W. Richardson, Washington, D. C., and Dr. William C. Woodward, Chicago, both representing the American Medical Association. No objection to the adoption of the reduction has thus far appeared from any source.

New County Society Presidents.—The following physicians have recently been elected president of the county medical society indicated:

Dr. Alfred R. Autrey, Port Arthur, Texas, Jefferson County Medical Society.

Dr. Francis B. Blackmar, Columbus, Ga., Muscogee County Medical Society.

Dr. Edwin G. Bloor, Antigo, Wis., Langlade County Medical Society.

Dr. Robert K. Buford, Charleston, W. Va., Kanawha County Medical Society.

Dr. Ebenezer P. Clapper, Waynoka, Okla., Woods County Medical Society.

Dr. Lawrence G. Clayton, Central, S. C., Pickens County Medical Society (reelected).

Dr. William M. Gambrell, Belton, Texas, Belle County Medical Society.

Dr. Edward W. Gray, Sheffield, Ala., Colbert County Medical Society.

Dr. John F. Harrison, Mexico, Mo., Audrain County Medical Society.

Dr. O. Paul Humpstone, Brooklyn, Medical Society of the County of Kings.

Dr. Oren M. Kramer, Millersport, Ohio, Fairfield County Medical Society.

Dr. Bruce D. Lung, Kokomo, Ind., Howard County Medical Society.

Dr. William C. Moser, Morgantown, W. Va., Monongalia County Medical Society.

Dr. William J. B. Orr, Smithfield, N. C., Johnston County Medical Society.

Dr. William G. Pittman, Pine Bluff, Ark., Jefferson County Medical Society.

Dr. Theodore J. Redelings, Marinette, Wis., Marinette-Florence County Medical Society.

Dr. Charles I. Shaffer, Ralphton, Pa., Somerset County Medical Society.

Dr. Lawrence Shields, Xenia, Ohio, Greene County Medical Society.

Dr. Henry M. Stuckey, Sumter, S. C., Sumter County Medical Society.

Dr. Frederick J. Swift, Maquoketa, Iowa, Jackson County Medical Society.

Epidemiologic Report of League of Nations.—The November 15 issue of this report shows a marked increase of plague in August and September in certain regions of southern India, where the maximum incidence usually falls in October; plague was much more prevalent in the Bombay presidency than at the same time last year; from August 23 to September 19, there were 3,543 deaths from plague in the provinces of India. An increase in plague is also reported in Java and Siam, but in the principal ports of Asia, the plague situation was good during October; there were sporadic cases in September and October in Greece and in Egypt; there was an outbreak in June in Nigeria, which up to the middle of October amounted to 407 cases, with 301 deaths.——The cholera epidemic in Shanghai reported recently seems to have ended, only one new case being reported during the last two weeks in October. The outbreak in Manila which decreased in October had amounted to 199 cases and sixty-nine deaths at the time of this report. The severe epidemic in Kashmir had caused 11,400 deaths up to September 19, being exceeded only by the outbreak in September, 1919. The Punjab was infected from Kashmir (which is rare) and there were 2,600 deaths from cholera there up to September 19.——Yellow fever has been more prevalent on the Guinea coast than in 1924.——Typhus continued to decline in eastern and central Europe during the autumn, the incidence being the lowest since the World War; no cases were reported this year in Austria and only two in Germany; there were fifty-one cases and two deaths in Poland in the month ending October 3.——Malignant smallpox has been extremely rare in Europe except in Spain, no death having been reported since June in any other European country. Smallpox caused 3,572 deaths in Mexico in the first eight months of 1925, the greatest prevalence being in Central Mexico. Smallpox overran most of India during the first half of this year; an outbreak seems to occur here every fifth year.——There was an increase in mild influenza in October in England and Wales, with 196 deaths in the four weeks ending October 17 as against sixty in the preceding four weeks. British Guiana had an outbreak of 650 cases of influenza in the month ending August 8; the disease seems to be affected little by seasonal influences, an outbreak occurring about every nine months.——Scarlet fever is on the increase in central Europe and Great Britain; there is no indication, however, that the epidemic will be more extensive than those which occur every few years, the last one being in 1921.——The general mortality has been favorable in European and North American cities, and is the lowest on record in German cities, and markedly improved in other parts of central Europe. Mortality, which in the last century was often excessive during the summer, is now usually the lowest at that time except in subtropical countries. Modern sanitation has been less successful in dealing with winter excess mortality, which is caused largely by influenza and other respiratory diseases.

FOREIGN

Personal.—Dr. William E. Gye has been awarded the annual fellowship established by London University for the graduate who has done most for the advancement of medicine in the last five years.

Campaigns Against Quacks in Japan.—The *Japan Medical World* states that the metropolitan police of Tokyo are now enumerating all quack doctors in that community, preparatory to launching a campaign to enforce the law against them. While investigations in October revealed only eighty-eight quacks practicing without a proper license, current reports place the number at several hundred. The law exacts only a fine of 500 yen for practicing without a license, which the quacks are said to be able to pay without much inconvenience.

Professor of Physiology at Cambridge Appointed.—Dr. Joseph Barcroft was appointed professor of physiology of Cambridge University in England, December 16. Professor Barcroft was president of the physiologic section of the British Association in 1920; was awarded the Royal Medal in 1922 and the Baly medal in 1923; he was the Oliver-Sharpey lecturer, Royal College of Physicians, in 1915; the Lowell lecturer in 1922; lecturer in Kings College, Cambridge, and reader in physiology in Cambridge; Fullerian professor of physiology at the Royal institution, and editor of the sixth edition of Huxley's Physiology.

Infant Mortality in Bombay.—In his last annual report, the health officer of Bombay showed that the infant mortality in that city in 1924 was 419 per thousand births, although, if the rate is calculated on the deaths of infants born in Bombay, it is reduced to 275, as 3,159 of the deaths were of infants born elsewhere. "This excessive emigration of the infants is due," says the *Medical Officer,* "to a custom among native women of going to the country for confinement. The chief causes of death were diseases of the respiratory system, debility and premature births, convulsions, diarrhea, smallpox and febrile diseases; other adverse factors were poverty, ignorance, malaria, and the practice of soothing babies by the administration of opium."

Death of Sir Richard Powell.—Sir Richard Douglas Powell, one of the king's physicians, died in London, December 15, aged 83. Dr. Powell became physician in ordinary to Queen Victoria in 1889, to King Edward in 1907, and to King George in 1910. He was emeritus lecturer on medicine in Middlesex Hospital, consulting physician to Brompton and Ventnor hospitals, and former president of the Royal College of Physicians; he delivered the Harveian oration in 1914 on "Advances in Knowledge Regarding the Circulation and Attributes of the Blood Since Harvey's Time"; was the author of "Diseases of the Lungs and Heart" and other publications, and had been a Knight of Grace of the Order of St. John of Jerusalem since 1898.

Government Services

Annual Report of Public Health Service

In the annual report of the U. S. Public Health Service submitted to Congress, Surgeon General Cumming states that preliminary figures indicate a death rate for the country in 1924 of about 11.9 per 1,000, as compared to 12.4 in 1923; with 17.6 in 1900 and with 19.8 in 1880. Heart disease ranks first in the United States as the cause of death and its incidence is steadily increasing. Influenza and pneumonia combined occupy third place. Infant mortality has shown an appreciable decrease, but the number of deaths of mothers incident to childbirth has shown little change in the last nine years for which data are available. From 1915 to 1922 inclusive, it is estimated that for every 100,000 babies born, the lives of from 600 to 900 mothers were sacrificed; about one-third of these deaths were caused by infection of the mother at childbirth. The diphtheria death rate shows a fall from 43.3 per 100,000 in 1900 to 12.1 in 1923. "If parents could be induced to protect their children by the use of the 'toxin-antitoxin' process of immunization," says Surgeon General Cumming, "there is no reason why diphtheria might not be still further greatly reduced or even exterminated." The death rate from tuberculosis in the registration area dropped from 201.9 per 100,000 in 1900 to 93.6 in 1923. Reports from thirty-five states having a population of nearly eighty-eight and one-half millions give a death rate of 88.6 for the calendar year 1924.

Reports from thirty-five states for the calendar year 1924 showed an increase of 75 per cent in the number of cases of smallpox and 628 per cent in the number of deaths as compared with the year 1923. The smallpox case-rate in the United States is at present, according to reports received, the highest of any civilized country in the world. It may be said, however, that much of the disease is of a mild type and in some countries many of these cases would be classed as "alastrim." It is also believed that smallpox is better reported in the United States than in most other countries. Eleven cases of tetanus, most of them fatal, occurred in the United States during the year as a result of the use of bunion pads as vaccination dressings. Efforts are being made to induce physicians to follow a standard technic when vaccinating, and warnings were issued against the use of shields and bunion pads as dressings.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 5, 1925.

Preservatives in Food

Mr. Neville Chamberlain, minister of health, speaking at a luncheon of the provision trade section of the London Chamber of Commerce, said that he recognized that the new regulations regarding the use of preservatives in food (The Journal, September 26, p. 988) might involve inconveniences, even some hardship, to individual members of the community, but the very last thing the government desired was to interfere with trade or industry. The crux of the controversy that had arisen was the plea for the removal of the prohibition of boron compounds. He would explain the considerations which had weighed with him in this matter. It was known that these boron compounds were poisonous, that they readily passed into the blood stream and were not excreted so quickly as they were absorbed, and they therefore had a cumulative effect. During the past forty years their use had been increasing, and there had been an increase in the prevalence of certain digestive diseases, such as appendicitis and dyspepsia. The retort might be that it could not be proved that these evils were due to boric acid; he could not prove it, nor could the traders prove that they were not. Before the cancellation of the prohibition could be urged, it was necessary to prove that this form of preservation was necessary, for if it was not necessary there was no point in the demand for further inquiry as to the effects of boron compounds. The trade had also to take into account that in certain countries the use of these preservatives was absolutely forbidden, except in a certain limited number of foods; and in all cases, although their use might be general, there were certain firms that had succeeded in doing without them. The case for prohibition was therefore unanswerable. There was considerable time to make the necessary adjustments and to consult with the transport companies and shippers.

Arsenic in American Apples

Shopkeepers in a London district were summoned for selling apples found to contain arsenic, in one case to the amount of one-fifth grain (0.13 gm.) to the pound (453 gm.). Owing to a case of illness reported to the local health authority as due to eating apples, samples were taken. Five of the samples of Jonathan apples imported from America were found to contain arsenic; in each case, more than a hundreth of a grain to the pound. Samples of English apples, taken in the district, were free from arsenic. It was pointed out that fruit growers in all parts of the world made a practice of spraying trees for the purpose of combating insect pests and that in America not only the blossom but also the fruit was sprayed on the tree. For the defense it was stated that in America the presence of the dreaded fruit tree pest known as the codling moth made it necessary to spray fruit trees with arsenic. The season had been unduly dry, with the result that the arsenic had not been washed off. Although the shopkeepers could not be expected to know anything about the arsenic they were, according to the law, fined in each case to the extent of $13, with $5 costs.

The Prevention of Venereal Diseases

Sir Arthur Newsholme, who for many years was principal medical officer to the ministry of health, delivered a lecture for the British Social Hygiene Council on "The Community and Social Hygiene." He was convinced that the control of venereal diseases should become a question of organizing public opinion and action against irregular sex relations.

For practical purposes these were solely responsible for such diseases. He regarded the general advocacy of prophylaxis in irregular sex relations as inimical to moral progress, by means of which, in conjunction with extended medical measures, we should render venereal diseases a shadow of their present self. In recent years, and particularly in the last decade, notwithstanding the terrible sexual lapses due to the Great War, the hope of controlling venereal diseases had become increasingly bright. Much good could result from the greater frankness with which sexual problems were discussed. He regarded public propaganda on preparations for prophylaxis in irregular sex relations as a sort of partnership in the projected immorality and as an encouragement of promiscuity In many departments of life there had been vast improvements in our sense of social responsibility. In sexual morality there was indubitable proof of improvement. One of the problems was to ascertain how an act, which even now was regarded as venial in a man and infamous in a woman, could by force of public opinion be made equally infamous for the two sexes. Facilities should be given to teachers to attend special courses of lectures on social hygiene and ethics, and conferences should be held between teachers and parents Biology, psychology and hygiene should be taught in all secondary schools. Sexual hygiene should take its place with other branches of public health education directed toward self-control as affecting health

Illicit Traffic in Narcotics

The extent of illicit traffic in narcotics, such as opium, morphin and cocain, is revealed in a report issued by the advisory committee on traffic in opium of the League of Nations More than 1,100 seizures of contrabrand drugs have been reported to the league during the last four years In the majority of cases seizures were made on board ships, where drugs are concealed in the most unsuspected and out of the way places, as, for instance, the lamps of the bridge compass, the water tank under the boilers, in barrels of smoked fish, casks of phenol (carbolic acid), tea chests with false bottoms, the cylinders of a life raft, under coils of rope in the wheel room, or in the soles of the shoes of the accused. In other cases the drug has been shipped as phonograph records or electric bulbs, or described as "salted pickles" or cocoa powder. Two large consignments of drugs were concealed in iron safes and iron beadsteads, respectively. The methods of concealment are most ingenious and involve considerable expense. Heroin in bedsteads seized at Hongkong was packed in tin tubes, specially made to fit the hollow legs of the bedsteads. Below the tubes, plugs had been soldered into the hollow legs, and below these the casters were screwed on.

MADRID

(From Our Regular Correspondent)

Nov. 12, 1925.

Medical Reciprocity with Foreign Countries

The army directory has issued a decree providing for reciprocity with foreign countries as regards the practice of the several professions, including medicine. Heretofore, it has seemed strange that this country should grant all kinds of facilities to foreigners, while Spanish physicians find so many handicaps when trying to practice abroad. The situation was the worst in precisely those nations in which large numbers of Spaniards make their homes. In fact, medical practice was practically prohibited to Spaniards, except in the rare cases in which physicians had studied there from grammar school on. Thus, in neighboring France, Spanish physicians can be counted on the fingers of both hands, and those few are the sons of emigrants or persons who have spent their entire lives there. Nationalist sentiment has been so aroused that a number of Spaniards, urged to settle in France during the World War, were compelled to leave the country afterward; forbidden to practice, in peace times, the very profession which they had been called over to aid in.

The present reciprocity measure had been demanded on several occasions by medical societies in the provinces bordering on France, as they have been the ones suffering most from the influx of foreign physicians. The government has now complied with their wishes, but has recognized the rights of those physicians settled in Spain before official publication of the new provisions.

A proof of the indifference shown by physicians even to their most vital problems is found in the scarcity of comment on such a far-reaching question. Only two articles have discussed the matter. In one, Dr. Cortezo, the editor of *El Siglo Médico* and president of the council of state, pointed out the possible danger of a rush of foreign physicians. Germany and Austria may now accept reciprocity, as their universities keep on training physicians while the loss of territory has decreased the available fields. Thus the German Reich could send 100 graduates to Spain for each Spanish physician going to practice in Germany.

In the other paper on the same subject, Dr. A. Fernández de Velasco regrets the lack of reciprocity agreements with Latin American republics. This point seems to have been overlooked in the recent decree. Among Latin American countries, only Bolivia, Colombia, Costa Rica, Honduras, Nicaragua, Peru and Salvador have so far signed such treaties. Panama is now considering the matter. The most important republics, such as Argentina, Chile, Cuba and Mexico, not to mention Ecuador, Guatemala, Paraguay, Santo Domingo, Uruguay and Venezuela, have taken no action on this matter. Reciprocity treaties prove influential in promoting university relations, as shown by the fact that the two countries having most students in Spain are Colombia and Peru, both of which enjoy reciprocity rights, while hardly any students come from the others. In Paris, there are nearly 7,000 Latin American students, and 20,000 Latin American families have trailed them there, spending millions of francs each year. In Spain, there are barely 200 Latin American students. Argentina shirks reciprocity on the ground that it has already an overflow of graduates. In a single Argentine medical school, that at Buenos Aires, the enrolment reaches 5,000. Cuba also declines reciprocity, alleging that if this privilege is extended to Spain, France and Italy will expect a similar courtesy. Porto Rico and the Philippines are out of the question, because of American control.

Pediatric Congress

The Spanish Congress of Pediatrics met with great success. A welcome departure was the active participation, in a medical meeting, of noted representatives of other professions, such as lawyers, judges, teachers and priests.

One of the most interesting papers was by Dr. González Alvarez on child welfare. He protested against the undue emphasis laid on the care of illegitimate children rather than of children in general. González Alvarez pleaded for compulsory breast feeding, a conclusion accepted by the congress only so far as it applied to mothers in lying-in hospitals. His other resolution, forbidding outside nursing by mothers who did not nurse their offspring, received endorsement. González Alvarez drew a somber picture of present Madrid employment agencies for nurses. These agencies are usually boarding houses. The rooms are small and overcrowded. Feeding utensils are promiscuously used. In order to keep the milk flow of unemployed wetnurses, two or three overgrown indigent infants are used. These children usually have rickets or scrofula, if not syphilis. If there are no children on hand, the other women replace them. In one recent case, the nursed baby acquired itch from one of these nurses. *In another* nurse, skin and mucous signs of syphilis were detected during her first month's employment. After dismissal, such nurses return to the employment agency to continue spreading disease, as no medical examination is enforced, and the provision requiring nurses to have health cards has long been neglected. In order to remedy such deficiencies, González Alvarez suggested the passage of a law, but with "teeth" in it, so that child health should really be protected.

Dr. Bandelac de Pariente of Paris stressed the advantages offered to young and visiting physicians in France by Umfia, the Franco-Iberic-Latin-American society.

The one mishap attached to the congress was the sickness, contracted during the meeting, of the surgeon Arquellada, who died a few days after his return to Madrid. Although still young, Dr. Arquellada, surgeon at the Niño Jesús (Children's) Hospital of Madrid, had made a name for himself through the introduction of several surgical methods. These he described in the child surgery congress held recently in Paris.

Farewell to a Clinical Professor

The Madrid Medical School witnessed recently an almost unprecedented scene, when Dr. A. Redondo, the professor of pathology and clinical medicine, reached the retirement age. His last lecture was attended by former pupils from all over the country, some of them now occupying high positions. Dr. Redondo was satisfied to be just a professor. He never tried to go into politics or to devote his talents to social problems. His only acquaintances were among his pupils, who now have shown the love and respect they feel toward their old preceptor. When the lecture was over, the whole audience surrounded the professor and went with him as far as the door of the school.

Fifty Years of Professional Life

For fifty years, Dr. S. Cardenal of Barcelona has practiced medicine and surgery. The authorities and scientific societies of his home town thought the occasion had come to show their recognition of such a useful career, which included the introduction of antisepsis in Spain. For the first time in the history of the city, such honors have been rendered to a physician. Dr. Cardenal's name was given to the hospital clinic where most of his surgical work has been done, and a number of meetings were held, with no end of laudatory speeches. Fortunately, Dr. Cardenal was strong enough to bear up with so much enthusiasm. As a practical way of showing his gratitude, he has endowed a fellowship, which will permit some meritorious young man to become a physician.

Aid to Physicians

Dr. Murillo, director general of public health, has issued an order that will secure indigent physicians free admission to the private ward at any government hospital. Heretofore, impecunious physicians in need of medical treatment had often been unable to secure admission to hospitals, as all free beds available were occupied.

First Spanish Medical Salon

A Madrid paper, *Vida Médica*, had the original idea of holding an exhibition of art works by physicians. A prerequisite was that the subject should not be medical. There were more than 300 entries, including paintings, sculptures, architectonic plans and even literary works and musical compositions. The exhibition was held in the rooms of the Society of Friends of Art, one of the most elegant and aristocratic places in town.

The king personally inaugurated the show, being accompanied by the whole army directory and the diplomatic corps. He proved himself a good critic in passing judgment on the exhibition. "I thought this exhibition would be rather humorous, but I see here a number of interesting works." The satirical writer A. Azpeitia has given expression to the alleged displeasure of patients at seeing physicians thus go into strange fields. "Physicians neglect their profession and devote themselves to dilettantism while we suffer. Physicians may go in for all kinds of amusements, provided they keep it quiet. Patients are naturally selfish and want to monopolize their physicians' attention. They do not want even to share it with other fellow sufferers."

On the other hand, Dr. Alvarez Sierra said: "There is no profession or class having so many receptive elements for esthetic emotion as physicians. . . . Every physician carries within him an artist's soul. Such artistic manifestations are safety valves offering an outlet to the nervous tension of those constantly walking in the footsteps of death." Dr. Juarros endorsed this view: "Pain, among its many qualities, has the power to take off all social masks. That spectacle of human zoological realism would embitter life, were it not for a romantic reaction on the part of the physician."

There is little doubt that this first attempt proved quite meritorious and compared favorably with other art exhibitions both here and abroad. If physicians now expressing their originality in lay fields ever devote a similar effort to their own profession, their success will prove astounding.

Nov. 18, 1925.

Cerebrospinal Meningitis

From his experience in the army of occupation, Dr. Muschang points out some facts concerning symptomatology of cerebrospinal meningitis. In addition to the outstanding symptoms, there are irregularity of the pulse, herpes labialis and petechial purpuric eruptions. In infants, abnormal tension of the fontanels is of high diagnostic value. Ocular signs, rapid coagulation of the cerebrospinal fluid and xanthochromia are of great importance. From the therapeutic standpoint, he recommends: (1) injection of serum into the vertebral canal; (2) prompt action; (3) large doses: withdrawal of 50 c.c. of cerebrospinal fluid, injection of 40 c.c. of serum, this dose to be repeated systematically for four days and combined with 40 c.c. of serum intramuscularly, and (4) specificity in the serotherapy: polyvalent serum, and, as soon as the laboratory has identified the causative meningococcus, injection of anti-A, anti-B or anti-C serum.

Free Tours to the Congo for Young Physicians

The *Bruxelles médical*, aided by a transportation company, has for some time been providing an opportunity for a number of young physicians and senior medical students to visit the Congo region. The young men selected are given a free passage in return for assisting the ship's physician.

Tartar Gingivitis in Relation to Cancer

Before the Société belge d'otorhinolaryngologie, Dr. Heyninx recently spoke on the concomitance of cancer of the respiratory and digestive tracts with alveolodental pyorrhea and gingivitis. There may be a relation of cause and effect between the two affections. Also, cancer of the tonsil may be secondary to a primary gum affection or the like. If the gum affection were of microbic origin, it might produce chronic irritation and result in hyperplasia of the mucosa which covers the tonsil. If neoplastic in origin, it would produce metastasis in the tonsil. Infected saliva might carry the virus into the throat and esophagus.

Resuscitation of the Heart

Dr. Schepens, in addressing the Société de médecine of Ghent, submitted a study of forty-three cases of reanimation of the heart by injection of epinephrin, twenty-three of which were successful. He concludes that this should become a routine method and that the surgeon should always have the necessary material at hand. Dr. Schepens gives, as conditions of success, not to lose precious time; to begin with a small dose (from 0.25 to 0.50 mg.), and not to interrupt artificial respiration.

Surgery of Ureteral Calculus

At the annual session of the Société d'urologie, several authors reported cases in which ureteral calculi had been removed by the extraperitoneal route. François and Tant reported several cases in which low position of the calculus makes possible the paraperitoneal route. The location of the calculus is determined by means of roentgenography and the opaque ureteral sound. Van den Branden referred to the vaginal route for the extraction of calculi.

Spina Bifida and Incontinence of Urine

Addressing the Société belge d'urologie, Dr. François pointed out the significance of spina bifida as a cause of incontinence of urine. Patients with incontinence of urine should be subjected to a roentgenologic examination with a view to detecting spina bifida of the fifth lumbar and first sacral vertebrae and metamerization of the sacral vertebrae. The discovery of malformation should be followed by epidural injection of iodipin through the sacrococcygeal hiatus or between the arches of the first lumbar vertebrae. It should then be determined whether or not the iodipin comes to rest near the site of the malformation.

In case of spina bifida and metamerization, with arrest of the iodipin at the level of the malformation, if the iodipin does not effect a great improvement, laminectomy of the sacral vertebrae and of the fifth lumbar vertebra, together with removal of abnormal processes (yellow ligament, fibrous adhesions, lipoma) that compress the dural culdesac may be considered if the patient is an adult. If the patient is a child, however, surgery should not be undertaken lightly—in any event, all other forms of treatment should be tried first.

The Problem of Heredity

In connection with the reopening ceremonies of the University of Brussels, Dr. Brachet, rector of the university, delivered an address on the present and future aspects of the problem of heredity. Numerous species of animals have become extinct. Evidences of previously unknown species are being discovered every day. Scientists have been able to classify animals and plants in accordance with a probable order of filiation. Some hold that reconstruction of the history of animals is possible. To be sure, methods now available for the construction of an historical biology are open to suspicion or nearly exhausted. It is the present living being that must be the object of research.

A Cruise in the Levant

The *Bruxelles médical* organized, some time ago, a successful Mediterranean tour. The Brussels journal is planning a second Mediterranean tour for the early spring. This voyage will take on an international character. The cost of the trip for physicians will be about 4,000 francs ($160).

Dr. Louis Coty and the Museum of Public Health

In the cemetery at Jemappes, a monument has recently been erected over the grave of Dr. Louis Coty, who was an active pioneer in public health work. Nearly twenty years ago Coty established the dispensary for ancylostomiasis, which has aided in eradicating that terrible disease, and the Museum of Hygiene at Mons, an organization for the education of the people. Museums usually contain monotonous exhibits which fail to attract the passer-by. The museum of Mons, however, essays to give practical instruction in problems affecting dwellings, foods and education. Numerous samples and some very significant pictures indicate the respective nutritive values of the essential food products.

The Society of Legal Medicine

At the reopening session of the Société de médecine légale of Belgium, the newly elected president, Professor Heger-Gilbert, took up the problem of stabilization of functions of medicolegal experts in courts, together with revision of fee schedules applicable to such experts. Suggestions for the modification of the present schedule were addressed to the Commission des frais de justice répressive.

BUCHAREST

Infant Feeding

In speaking before the Medical Society of Oradea Mare on infant feeding by means other than its mother's milk, Dr. Bálint distinguished between what he calls "substitute" and "artificial" feeding. The former he regards as feeding with milk from another woman or after modification from some other animal; the latter he defined as feeding with preparations artificially manufactured from milk or from other products. He gave an account of the laboratory methods of modifying milk in accordance with physicians' prescriptions. Artificial feeding is condemned by Bálint, and the majority of foods on the market are strongly decried. The great evil of them all is the ease with which they can be used. They are readily digested, but this is largely because they contain so small an amount of food material. Disorders arising from imperfect feeding escape for a long time the notice of the parent. Such children are pallid, flabby and listless, and lack resistance against disease. The market is flooded with infants' foods, all more or less likely to produce rickets and other nutritional diseases, and their banishment from nurseries would greatly aid the development of the race.

Hygienic Dwellings for Working Men

Hygienic dwellings for working men and chiefly for agricultural laborers in Roumania have been provided since 1919 by means of government grants, a sum having been included for that purpose in each year's budget. The annual expenditure from 1919 to 1924 amounted to $15,000, but the demand for cottages grew until this year the annual grant was increased to $24,000. As it is certain that this amount also will prove inadequate, an act will be passed that will authorize the conversion of $24,000 capital into interest, thus making it possible to build about 1,000 cottages yearly. Another clause of the same act provides that in the case of land being sold by the local authorities to laborers for building purposes, all the necessary plans, surveys and contracts are to be made by the minister of agriculture at state expense. The interests of the laboring classes are safeguarded by the act in a variety of other ways. For instance, land selected for building purposes must be suitable as regards soil, air and drinking water; and speculation by the builder or contractor is forbidden. Conditions of the sale or loan, terms of the loan and the general plan must be favorable to the laborer. During the period allowed for repayment, the property cannot be seized for debt, divided, encumbered or alienated in any way; exemption from taxation is granted for fifteen years. Preference is given in selection of sites to applications coming from localities which make a free grant of land either for house or for gardens. Materials are forwarded at cost price on government railways, but state assistance is granted only for buildings designed to accommodate one family. Each cottage occupies a plot of from 1,000 to 1,200 square yards, and the cost of building varies from $200 to $350. Loans may be repaid in annual instalments, extending over twenty or twenty-five years. Under the act of 1920, 7,500 workmen's cottages were built in one year. Another result of this act has been to abolish land speculation, and to keep down the cost of building sites. Owing to the fact that most Roumanian parishes own the adjacent country, which formerly was used as common land to supply fuel and pasturage, this land is now convenient for the erection of workmen's dwellings.

But the care of the state is not confined only to the housing of agricultural laborers. A law has been passed which authorizes the construction of houses in the larger cities for employees of both state and private enterprises, the government undertaking the building of the houses, setting aside a sum for that purpose. Actual construction will begin in 1926. The average building cost of a two-room flat is $640; the average yearly rental amounts to $50. A flat of three rooms and kitchen costs from $950 to $1,000, and may be rented for $60 a year.

Psychoses Associated with Migraine

At the Medical Society of Cluj, Dr. Jacobi read a paper on psychoses associated with migraine. He said that simple hemicrania sometimes develops mental irritation, depression, anger or slight hallucinations. With migraine of an epileptic type a visual aura can precede an attack. The true epileptic nature of migraine is noted when the visual aura becomes red. Abortive attacks, psychic symptoms or a psychic equivalent can occur. A transitory psychosis sometimes follows or accompanies migraine. This is important as indicating the necessity of antiepileptic treatment for migraine. Dr. Jacobi notes close clinical relationship between migraine and hysteria major. Several types of cases are on record; among them: (1) a combination of hallucinations of sight, confusion, amnesia or ataxia or aphasia, with attacks of migraine lasting six hours; (2) confusion, with religious delirium; (3) hemicrania, with temporary blindness, paresthesia and a speech disturbance, and (4) hemicrania after mental shock, with anxious delirium and disturbance of consciousness for three days. The occurrence of these psychoses is rare.

Detection of Yeast Extract as an Adulterant of Meat Extract

The *Revista Farmaciei*, a pharmaceutic journal, publishes a method by which one is enabled to detect as little as 1 per cent. adulteration of meat extract with yeast extract. This may act as an efficient check to dealers working off stocks of yeast extract as genuine meat extract. Such stocks are known to have been hurriedly withdrawn from the market since the test was published. If the sample gives a doubtful or negative result by that test, but is still open to suspicion, one may take from 3 to 6 gm. and dissolve it in 3 or 6 c.c. of water, according to the quantity taken; to this one may add sufficient spirit—methylated will answer the purpose—to throw down all that is insoluble in alcohol. After a vigorous shaking, one may separate the insoluble residue by decanting or filtering, dissolve this residue in 60 c.c. of water, filtered if necessary, and proceed as before. If the yeast extract is present, the characteristic bluish-white precipitate will be thrown down, on boiling with the modified Fehling's solution; this may be collected and weighed.

Government Attack on "Patent Medicines"

The postoffice department of Roumania has decided to establish a censorship over newspapers in an endeavor to prevent publication of offensive or fraudulent advertising. Newspapers printing such advertisements will be barred from the post. The advertisements aimed at are chiefly those of the lowest class of "patent medicines," about fifteen of which are at present being examined by the chemical laboratory of the ministry of sanitation to see whether they correspond with the claims made. This censorship has been in existence in Austria for some time, and has long been advocated in the medical journals as a public necessity.

VIENNA

Observations on Brain Abscesses

Dr. Winckelbauer recently addressed the Vienna Gesellschaft der Aerzte on the brain abscesses observed by Dr. Brunner and himself at the Eiselsberg clinic. He emphasized the frequency of recurrences and the consequent gravity of the prognosis. Frontal brain abscesses are adjacent to the accessory sinuses of the nose. Injuries of the frontal region are accordingly dangerous, as was observed in two cases that ended fatally in spite of repeated operations. In both cases pus had been retained but was not discovered at the repeated operations. Such abscesses should be drained at the lowest point, so that pus retention may be prevented as far as possible. An abscess sometimes takes as much as five weeks to develop, while in other cases it is manifest on the third or fourth day. In the discussion that followed the address, Dr. Jerusalem stressed the need of early diagnosis and early operation, as was shown by the experiences of the war. Otogenous abscesses, particularly those of the frontal and temporal lobes, as discussed by Alexander, are more favorable than abscesses of the cerebellum. The mortality from operations in frontal abscesses and those of the temporal lobe ranges from 40 to 50 per cent., while in cerebellar abscesses it runs as high as 90 per cent. Abscesses of the temporal lobe are drained from the middle ear, the lowest point; but cerebellar abscesses can be operated on only from the side. Otologists also extol drainage from the lowest point. Beck held that the variety of pyogenic agent is important in the prognosis. It is his experience that fetid, green, crummy pus offers a more grave prognosis than pus mixed with mucus. In the latter case a pyogenic membrane is present, so that the abscess can be better controlled.

The Seventieth Birthday of Professor Dimmer

The medical department of the University of Vienna celebrated, a few days ago, the seventieth birthday of Prof. Dr. Dimmer, an authority in ophthalmology. He studied under Nolte and Jäger, and served as an assistant under Fuchs. In 1885, he was called to a chair in Innsbruck; in 1900 he removed to Graz, and in 1910 he became Schnabel's successor in Vienna, where he took over the management of the First Eye Clinic. In 1918 Professor Fuchs retired and Dimmer succeeded him, while Meller assumed Dimmer's previous position. Dimmer's principal activity in ophthalmology has had to do with the normal and the diseased fundus, and, more particularly, with the histologic interpretation of many conditions not explainable solely with the ophthalmoscope. His researches have been on the detailed structure of the macula, its reflexes and the reflexes of the fundus as a whole. In the controversy with Gullstrand over the color of the macula, he appears to have been victorious. Photography of the fundus was first developed by Dimmer; his apparatus gives good service. His most important publication is "Der Augenspiegel," which is a complete treatise on modern ophthalmology. As a teacher, he stresses exact correction of the eyes, and his lectures are a model of exactness; likewise his operations betray almost pedantic exactness. As Professor Dimmer himself—possibly by reason of excessive modesty—resisted all urgings to participate in the festivities, his natal day was celebrated in his absence, by his many friends, admirers and colleagues.

Accidents Due to Electricity and Treatment in Electric Shock Simulating Death

In a lecture forming a part of the Vienna "Seminar-Abende" for general practitioners, Professor Jellinek discussed recently the etiology, pathology and treatment of accidents due to electricity. He attaches great importance to insulation of electrical household utensils, as, through short circuits, accidents may easily arise even with a low voltage (from 110 to 220 volts). Lamps, flatirons, cooking utensils, and, more recently, radio apparatus have been the cause of such accidents. Injuries actually due to electricity are not true burns; only an arc light can produce burns. Wounds due to electricity are generally grayish white, circular and firm, without a trace of reactive inflammation in the adjoining area. The hairs next the wound are not even singed, and, if the patient survives, the wounds are not in the least painful. There is not always a continuous lesion and almost never a severe or suppurating infiltration of the surrounding area—not even in injuries of the bones and joints. After a latent stage possibly of several weeks, an aseptic necrosis sets in, without any general manifestations, even though there has been extensive loss of substance or so-called spontaneous amputation. If such injuries are treated conservatively, the prognosis is very good. Surgery is contraindicated for two reasons: (1) during the first few days or even weeks, it is impossible to determine the extent to which degeneration of the tissues may occur; (2) the vessel wells, even at some distance from the electrical injury, sometimes are very vulnerable, so that severe hemorrhages may be induced. Scar tissue after such accidents is soft, is vascular and never shrinks, and is thus very favorably constituted. The strength and character of the current are not the sole factors in determining the intensity of the injury. The range of individual susceptibility is great; it varies in the same individuals on different occasions. What is termed "death from electricity" is, as the Vienna school has shown, in reality only apparent death. Necropsy reveals only agonal phenomena, such as edema of the brain or lungs and extravasations, but no explanation for the fatal outcome is found. Jellinek thinks that disturbance of function of the vital organs causes death. Support for this belief is found in the fact that persons who survive electrical accidents never show evidence of loss of organs even when they have lain like dead for hours. If the patient recovers, his restoration is rapid, once it begins. The sovereign remedy is artificial respiration, but this remedy must be applied as soon as possible after the accident and may need to be continued for many hours. Until death spots appear, there is still hope, even though the current was very heavy. All this is true likewise of injuries from lightning. Cases are recorded in which the first attempts at resuscitation were begun a full hour after the patient was struck by lightning, while another hour passed before the efforts were successful.

Trachoma, Anthrax and Typhoid in Austria

During the last few weeks, there have been three epidemic outbreaks of infectious diseases in the immediate vicinity of Vienna. The recent outbreak of typhoid in Neunkirchen has involved thus far ninety-two cases and has resulted in five deaths. The source of the infection was the milk from a small dairy. Two carriers came in contact with the milk. The outbreak of trachoma occurred in a factory near Vienna, in which not only native workmen but others from Slavic territory were employed. About twenty patients were hospitalized, and the factory was closed; this ended the outbreak. The epidemic of anthrax, to be sure, comprised only seven cases, but the infection had been carried into several districts. The infection started in a brush factory, and the unusual character of the disease gave rise to a certain degree of laxity, but the authorities soon got things in hand.

Marriages

Walter Peters Gardiner to Miss Catharine Marion Sullivan, both of New Orleans, December 2.

Russell Ethelbert Palmer to Miss Suzanne Brisbois, both of St. James, Mich., in November.

George Elisha May, Boston, to Miss Winifred Arnold of Wyoming, N. Y., September 24.

Stephen Jay Spitzer, New York, to Miss Elizabeth Noyes of Oakland, Calif., December 9.

Deaths

Henry Redwood Wharton ⊕ Berwyn, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1876; member of the American Surgical Association; formerly clinical professor of surgery at the Woman's Medical College of Pennsylvania, Philadelphia; at one time on the staffs of the Presbyterian, Children's and Bryn Mawr (Pa.) hospitals; author of "Textbook on Minor Surgery and Bandaging"; aged 72; died, December 3.

George French Little ⊕ Brooklyn; Medical Department of Columbia College, New York, 1895; member of the American College of Physicians; formerly assistant clinical professor of pediatrics, Long Island College Hospital; at one time on the staff of the Kings County Hospital; aged 60; died, December 5, at the Methodist Episcopal Hospital.

William Eck Doran ⊕ Colon, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1904; formerly president of the board of education; served in the M. C., U. S. Army, during the World War; aged 46; died, December 6, at the Sturgis (Mich.) Memorial Hospital, of erysipelas.

Henry Tierney Bray, New Britain, Conn.; University of Vermont College of Medicine, Burlington, 1902; member of the Connecticut State Medical Society; chairman of the board of health; on the staff of the New Britain Hospital; aged 46; died, December 7, following an appendectomy.

Lewis Cass Taylor ⊕ Springfield, Ill.; Bellevue Hospital Medical College, New York, 1875; past president of the Illinois State Medical Society; secretary, state department of registration and education; formerly member of the state board of health; aged 71; died, December 14.

Walter Gohring Ryon ⊕ Poughkeepsie, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1896; member of the American Psychiatric Association; superintendent of the Hudson River State Hospital since 1917; aged 51; died, December 4.

Albert E. Acker, Jacksonville, Fla.; Georgetown University School of Medicine, Washington, D. C., 1907; member of the Florida Medical Association; served in the M. C., U. S. Army, during the World War; aged 61; died, November 25, following a long illness.

Lavine Alonson Bromley, Granville, N. Y.; University of Vermont College of Medicine, Burlington, 1882; member of the Medical Society of the State of New York; aged 68; died, December 2, at the Glens Falls (N. Y.) Hospital, of heart disease.

Amos H. Horn, Putnamville, Ind.; University of Virginia Department of Medicine, Charlottesville, 1883; member of the Indiana State Medical Association; aged 68; died, December 6, at the Putnam County Hospital, Newcastle, of pneumonia.

John Rogers Parry, Jr., Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1911; served in the M. C., U. S. Army, during the World War; aged 35; died recently, at the Misericordia Hospital, of pericarditis.

A. A. Smith, Hawkinsville, Ga.; Savannah Medical College, 1875; past president of the Medical Association of Georgia; for eight years member of the state board of medical examiners; Civil War veteran; aged 78; died, November 26.

Howard Eugene White, Logan, Ohio; College of Physicians and Surgeons, Chicago, 1888; for eight years postmaster of Fairmont, Ill.; formerly bank president; aged 61; died, December 1, of pernicious anemia.

Henry M. Moulton ⊕ Cumberland Center, Maine; Dartmouth Medical School, Hanover, 1889; Medical School of Maine, Portland, 1889; formerly member of the state legislature; aged 61; died, November 22.

Charles E. Rogers, Gray Court, S. C.; University of Tennessee College of Medicine, Memphis, 1886; member of the South Carolina Medical Association; aged 67; died, December 3, of cerebral hemorrhage.

Charles Harrison Lee, Fayette, Mo.; Barnes Medical College, St. Louis, 1893; member of the Missouri State Medical Association; aged 52; died, November 28, at St. Joseph's Hospital, Kansas City.

Michael Joseph Burke, New York; Medical Department of the University of the City of New York, 1875; member of the Medical Society of the State of New York; aged 75; died, November 27.

Percy Eugene Riley ⊕ Eau Claire, Wis.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1903; aged 49; died, December 2, of cerebral hemorrhage.

Clarence L. Mershon ⊕ Fairhope, Ala.; Drake University College of Medicine, Des Moines, 1898; past president of the Baldwin County Medical Society; aged 54; died, November 26.

John Alexander Cox, Donaldson, Ark.; Memphis Hospital Medical College, 1889; member of the Arkansas Medical Society; aged 53; died, November 29, at a hospital in Little Rock.

George W. Schwartz, Summer Hill, Ill.; St. Louis Medical College, 1873; member of the Illinois State Medical Society; aged 78; died suddenly in November, of cerebral hemorrhage.

Edward B. Mouser, Electra, Texas; University of Louisville (Ky.) School of Medicine, 1898; at one time mayor of Electra; aged 50; died, December 2.

Edward Harris Scatchard, Sewickley, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1901; aged 49; was found dead, December 1.

Joseph Leo Gavin, Boston (licensed, Massachusetts, 1898); aged 55; died, November 29, at the Peter Bent Brigham Hospital, of heart disease.

James O. McDowell, Sumner, Ill.; Eclectic Medical Institute, Cincinnati, 1874; aged 82; died, November 28, at the Olney (Ill.) Sanatorium.

Maximillian Charles von Groll, Boston; Tufts College Medical School, Boston, 1898; aged 52; died, November 11, of chronic myocarditis.

John W. Wilhoit, St. George, Kan.; Northwestern Medical College, St. Joseph, 1885; formerly county coroner; aged 72; died, November 28.

William M. Durham, Jr., Woodville, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1906; aged 42; died, November 29.

Almarian W. Dyer, Butler, Ill.; Starling Medical College, Columbus, Ohio, 1883; aged 72; died, December 2, of carcinoma.

Benjamin F. Holliday, Atlanta, Ga.; Southern Medical College, Atlanta, 1894; aged 59; died, November 29, at a local hospital.

Parker T. Trowbridge ⊕ Hayward, Wis.; Milwaukee Medical College, 1910; aged 38; died, in November, of heart disease.

Thomas W. Harris, Eugene, Ore.; University of California Medical School, San Francisco, 1875; aged 77; died, November 30.

Oliver B. Richards, Nova, Ohio; University of Wooster Medical Department, Cleveland, 1874; aged 76; died, December 3.

Charles Edward Page, Melrose Highlands, Mass. (years of practice); Civil War veteran; aged 85; died, November 23

Louis Feldman, Brooklyn; Long Island College Hospital, Brooklyn, 1910; aged 46; died, December 3, of heart disease.

Elison V. Buckley, Senath, Mo.; Willamette University Medical Department, Salem, 1881; aged 74; died, October 20.

Charles Lee Nollau, Henderson, Ky.; University of Louisville School of Medicine, 1901; aged 45; died, December 3.

Dave C. Sanders, Boswell, Okla. (licensed, Oklahoma, under the Act of 1908); aged 74; died, November 27.

John Leonard Marsh, Brownsburg, Ind.; Medical College of Ohio, Cincinnati, 1874; aged 74; died, December 4.

Elias Kline Boltz ⊕ Lebanon, Pa.; Jefferson Medical College of Philadelphia, 1896; aged 54; died, August 19.

Felix G. Thornton, Knightsville, Ind. (licensed, Indiana, 1897); aged 75; died, December 8.

Norman Hull, Howard, Ohio (licensed, years of practice); aged 85; died, November 24.

Correspondence

SYNERGISM OF MAGNESIUM SULPHATE AND MORPHIN

To the Editor:—In THE JOURNAL, November 7, appeared an article by Dr. Gwathmey which he describes as a reply to my work on the alleged synergism of magnesium sulphate and morphin. There are three tables. Table 1 furnishes data of a case in which the patient experienced greater relief from pain when given morphin plus magnesium sulphate than when given morphin alone. This mere fact does not, however, constitute proof that simple addition did not bring about this result; indeed, the second longest period of relief was experienced in one of the two instances only in which magnesium sulphate alone was used. Tables 2 and 3 comprise lists of cases in which the time before postoperative sedative was shown to be longer when morphin plus magnesium sulphate was used preoperatively than when morphin was used alone. Here again there is no evidence of synergism. Both experimental and clinical literature offer abundant proofs that magnesium sulphate is a powerful sedative, which evidence I have never sought to question; in fact, I have published certain observations of the powerful depressing effect it has on dogs. However, that the salt has the ability to raise specifically the sedative power of morphin either in dogs or in man, I do hold to be not proven.

Dr. Gwathmey's discussion of the synergism of magnesium sulphate and ether and his introduction of procain into the magnesium sulphate-morphin mixture serve only to confuse the studies. HARRY BECKMAN, M.D., Milwaukee.

Acting Director, Department of Pharmacology,
Marquette University School of Medicine.

"SYMMETRICAL CYANODERMA"

To the Editor:—In the Rio de Janeiro letter (THE JOURNAL, November 28) appears the abstract of a report by Dr. Moreira de Fonseca, dealing with a matter entitled symmetrical cyanoderma.

The description of the eruption is meager, but, judging from the brief account, the lesions and their mode of involution are very strongly suggestive of an eruption due to either phenolphthalein or antipyrin, administered by mouth.

It would be unwise to burden our overcrowded dermatologic nomenclature with the term "symmetrical cyanoderma," for it might be readily confused with such diseases as erythromelalgia, Raynaud's disease, pernio and erythredema.

FRED WISE, M.D., New York.

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

AUTOMOBILE ANTIFREEZING SOLUTIONS

To the Editor—What are the most commonly used antifreeze mixtures and what are their advantages and disadvantages? What are the percentages of ingredients to prevent freezing in this locality? Please omit name. T. H. P., M.D., Chicago.

To the Editor.—About a year ago I saw an answer to a query in regard to an antifreezing solution for use in winter in our cars. This article I have mislaid and cannot find. Would you be kind enough to send me that formula and inform me as to whether it evaporates, injures a radiator, at what point it boils, at what point it freezes and how strong a solution should be used? Or if you have by this time a better formula, you may send me that one. There are several on the market at this time made from a glycerin base but they are all expensive. If published, use initials only.

C. P. S.

Answer:—There are five types of antifreezing solutions for automobile radiators in use, each of which has certain advantages and disadvantages:

1. Alcohol (denatured). This is in most common use, approximately 28,000,000 gallons having been consumed in the United States for this purpose in 1924-1925. It has the advantages of being readily obtainable, of depressing the freezing point, and of having a satisfactory viscosity. The "strength" of the alcohol-water solution in the radiator can be measured by means of an hydrometer. Its shortcomings are that it has a lower boiling point than water; therefore, if proper precautions are not taken it will boil over; the solution loses its nonfreezing properties through continued use by evaporation of the alcohol, as a result of the relatively high vapor pressure. The alcohol vapors from overheated radiators are also inflammable, and the denaturants used are often obnoxious. Alcohol attacks automobile finishes.

2. Glycerol (glycerin). Glycerol, which should be of a relatively good grade, has the advantages that, once introduced into the radiator system in aqueous solution, it remains there unless lost through leakage or is removed intentionally; that is, it does not lose its effectiveness from use. Moreover, it is odorless and does not have the solvent action on finishes, as has alcohol. On the other hand, it is somewhat more expensive than alcohol, and as it is a by-product it is doubtful whether production can be increased sufficiently to meet the demand if it replaces alcohol. There has been an erroneous opinion that glycerol attacks the rubber connections. According to H. S. Corth (*Pharmaceutical Era*, Feb. 14, 1925, p. 212), the explanation is that some radiator hose is swelled by water. When this happens, the holding clamps dent into the hose. Glycerol tends to cause the hose to return to its original size, but the dents made by the clamps will remain in the rubber. The obvious cure, of course, is to tighten the clamps.

The following table, worked out by the Bureau of Standards, gives the temperature at which freezing starts, showing glycerol and alcohol to be of about equal value in lowering the freezing point:

Per Cent. by Volume	Glycerol	Denatured Alcohol
10	29 F.	27 F.
20	21	19
30	12	10
40	0	— 2
50	—15	—18

It should be remembered that solutions of both of the foregoing go through a mushy state before they get solid, so that a solid block of ice would not be formed until 10 or 15 degrees F. below the temperature given in the table.

The boiling points are as follows:

Per Cent. by Volume	Glycerol, Boiling Point, ° F.	Per Cent. Glyc. in Vapors	Alcohol, Boiling Point, ° F.	Per Cent. Alcohol by Weight in Vapors
10	214	0	199	49
20	216	0	190	64
30	217	0	187	71
40	221	0	183	76
50	225	0	181	80

3. Glycerol and Alcohol Mixtures: These are more satisfactory than alcohol alone because there is less loss of alcohol by evaporation; they are less expensive than glycerol alone because of the less amount required. To a certain degree they have some of the disadvantages of both alcohol and glycerol; one drawback is that the "strength" of the solution cannot be tested by an hydrometer because it contains three components.

The following table, taken from the *Pharmaceutical Era* (Dec. 6, 1924, p. 595) gives the freezing temperatures of alcohol-glycerol mixtures as:

Alcohol	Glycerol	Water	Freezing Point
15%	15%	70%	zero
16%	16%	68%	5 below
20%	20%	60%	20 below

4. Glucose or Honey Mixtures; Calcium Chlorid Mixtures: Glucose has been reported with success by a number, while others have found that it becomes "slushy" when the temperature is near zero, or that it causes overheated engines. It was thoroughly discussed in The Journal last year (Oct. 25, 1924, p. 1356; Dec. 13, 1924, p. 1942; Dec. 13, 1924, p. 1943; Dec. 27, 1924, p. 2113).

Calcium chlorid has also been used, but has generally been discarded because of its action on the metal.

5. Miscellaneous; Kerosene and Ethylene Glycol: Kerosene can be used with advantage in climates where the weather is severe. In warmer climates it causes a greatly overheated engine on warm days because of its poor properties of heat transfer. As there is no vaporizable component, the motor meter probably would not indicate high temperatures in the radiator system.

A new substance, ethylene glycol, has been proposed. From the research work done, it has promise of being of considerable merit (Ethylene Glycol; Curme, George, *Indust. & Engin. Chem.*, November, 1925, p. 1117). It possesses the advantages of alcohol and glycerol combined. It does not act on metals, is permanent, and has physical properties that permit maintenance of optimal engine temperature. It is not yet available in many localities, but large quantity production is promised. It requires a little less amount (by volume) than denatured alcohol for the same freezing points.

TRANSPLANTATION OF THE CORNEA

To the Editor:—Has there been reported a case of transplantation of the cornea? Please help me go over the literature. I will be much obliged for the information. I happen to think of this because I know of a friend who had a traumatic opacity of the cornea of his right eye, and all hopes were given up for recovery. If skin could be transplanted and grow, why could not the same thing happen with corneal transplant?

R. T. Altura, M.D., Detroit.

Answer.—Much work has been done with regard to the transplantation of corneal tissue to replace scarred cornea. A bibliography of all important articles to 1921 is appended, the most important ones being starred. Of all of the keratoplastic operations, the von Hippel through and through trephine operation has proved the most successful, particularly in the hands of Elschnig and his assistants. The latest report from that clinic concerned 115 cases in which corneal transplantation had been done. Economically useful vision was restored in approximately 10 per cent. of the cases; no change in vision occurred in about 65 per cent.; the vision became worse in about 15 per cent., and the eye was lost in about 10 per cent. The factors determining the success or failure of the operation could not be determined (apart from lack of strict asepsis), and the end-result did not become apparent until about six months had elapsed after operation.

SCHNABEL'S METHOD OF OCULAR DIAGNOSIS

To the Editor:—Can you give me any information concerning the methods of Dr. Rudolph Schnabel of Munich, in his examination of the eye? I am informed that he makes many extraordinary claims as to the information which he can gain through an examination of the eye with his iridoscope. Some remarkable photographs of the human eye, magnified many times, were recently shown to me by one of his co-workers. My impression is that there is much truth in many of his assertions, but that many of his deductions are unjustified. Any information which you can supply me concerning this subject will be much appreciated.

J. J. Short, M.D., New York.

Answer.—A letter from Munich in the *Deutsche medizinische Wochenschrift* states that the Munich Aerztliche Verein recently devoted a session to "Homeopathy and Eye-Diagnosis," as both are much the fashion there at present and popular among the public. In the center of general interest is diagnosis by inspection of the eye, which is practiced partly by registered physicians, partly by laymen, partly with all modern equipment of apparatus, partly with the simple ophthalmoscope, but always with much success, according to the one making the diagnosis. Dr. Salzer, the professor of ophthalmoscopy, read the paper on this "So-Called Eye Diagnosis," and, the author remarks, "die wissenschaftliche Wertlosigkeit dieser Methode trat damit klar zutage" (the scientific worthlessness of this method was made very plain by what he said). . . . "Professor Salzer invited an eye-diagnosis colleague to a public test of his method, but the invitation has not been accepted."

DISTRIBUTION OF WHITE AND COLORED PHYSICIANS

To the Editor:—Would it be possible for you to get for us through your office, or tell us where we could get, the number of male white physicians in the United States in 1924, by States, and for the following cities: New York, Chicago, Philadelphia, Los Angeles, Cleveland, Boston, Detroit, Baltimore, St. Louis and Pittsburgh? We need these figures for the study of deaths among physicians by age groups and would be grateful if you could help us out.

HARRIET HUGHES, New York.

ANSWER.—The following table lists as nearly as possible the number of white and colored physicians in each state:

	Colored	Male and Female, White (Estimated)
Alabama	163	2,121
Arizona		378
Arkansas	95	2,117
California	25	8,338
Colorado	6	1,831
Connecticut	9	1,875
Delaware	17	239
District of Columbia	150	1,663
Florida	94	1,358
Georgia	255	2,867
Idaho		416
Illinois	132	10,611
Indiana	30	4,221
Iowa	5	3,373
Kansas	40	2,324
Kentucky	153	2,888
Louisiana	134	1,857
Maine		1,037
Maryland	73	2,240
Massachusetts	59	6,128
Michigan	42	4,795
Minnesota	12	2,811
Mississippi	107	1,595
Missouri	152	5,654
Montana		525
Nebraska	11	1,858
Nevada		129
New Hampshire	3	598
New Jersey	99	3,468
New Mexico	2	363
New York	175	17,496
North Carolina	254	2,027
North Dakota		285
Ohio	77	7,036
Oklahoma	180	2,344
Oregon		1,176
Pennsylvania	188	10,952
Rhode Island	11	760
South Carolina	153	1,164
South Dakota		604
Tennessee	154	2,974
Texas	180	5,883
Utah		505
Vermont		537
Virginia	200	2,334
Washington	3	1,778
West Virginia	69	1,684
Wisconsin	2	2,824
Wyoming		255
Total	3,514	143,496

ACNE ROSACEA

To the Editor—Please give me information concerning the treatment of acne rosacea, including the administration of the endocrine gland products. Please omit my name.

T. J R, Kentucky.

ANSWER.—Several factors have to be considered in the treatment of acne rosacea Errors of diet and gastro-intestinal disturbances of other sorts are contributing factors, and an examination has to be made to determine the presence or absence of these and treatment instituted according to the findings. Occasionally desiccated thyroid (thyroideum siccum U S. P.) is of service in women at the climacteric period. This should not be given, however, without determining its propriety by having a basal metabolism test made. Local treatment is of service but has to be regulated according to the character of the symptoms present. These are variable in different cases.

Pennsylvania July Examination

Mr. C. D Koch, director of professional education, Bureau of the Pennsylvania Board of Medical Education and Licensure, reports the oral, written and practical examination held at Philadelphia and Pittsburgh, July 7-11, 1925. The examination covered 5 subjects and included 50 questions. An average of 75 per cent. was required to pass. Of the 289 candidates examined, 273 passed, and 16 failed Eight candidates were licensed by reciprocity, and 4 by endorsement of credentials The following colleges were represented:

Book Notices

The Anatomy of the Root-Canals of the Teeth of the Permanent Dentition. By Walter Hess, M.D., D.D.S., Professor of Operative Dentistry in the Dental College of the University of Zürich. The Anatomy of the Root-Canals of the Teeth of the Deciduous* Dentition, and of the First Permanent Molars. By Dr. Med. Dent. Ernst Zürcher, School-Dentist of Zürich. Cloth. Price, $5.50. Pp. 199, with illustrations. New York: William Wood & Co., 1925.

The authors have divided their book into two main parts, the first dealing with the anatomy of the root-canals of the permanent teeth. The first author gives a thorough review of the previous literature concerning the subject and then describes in detail the technic used in his own researches. Each tooth of the permanent set is given a separate chapter in which the minute anatomy of its root-canal is described, with a tabulation of the number of teeth examined, the number of canals found, the apical ramifications, the marrow canals, and the average percentage of each. In making this study the author has examined 2,800 teeth in persons ranging in age from 5 to 55 years. This part of the book is profusely illustrated, and credit should be given the publishers for their careful treatment of the illustrations. In the second part, the anatomy of the root-canals of the deciduous teeth, the author's treatment has been the same, and there are many beautiful illustrations. Since the proper treatment of disease of the dental pulp and of canals is based on the anatomy of the parts, every dentist who attempts such treatment should be thoroughly familiar with this excellent work. The anatomy of dental pulp is a most important factor in the problem of the pulpless tooth and its relation to systemic disease. All interested in this subject will find valuable material for study in this volume.

The Nursing of Eye Cases. By Louise Kingham, S.R.N., Matron of the Weymouth and Dorset County Royal Eye Infirmary. Paper. Price, 50 cents. Pp. 16. New York: Oxford University Press.

There can be no question in the mind of the reader of this pamphlet that Miss Kingham is an efficient and capable ophthalmic nurse; but she does not tell any one else how to be. The anatomy of the eye is described more briefly and in a more elementary manner than is usual in a grammar school physiology, although words of more than one syllable are used. Some of the commoner diseases of the eye are mentioned, and the treatment of each is spoken of briefly. But the treatment described is that employed by the surgeon, while the nurse is warned that she must not "even put drops in an eye without an order from the surgeon." The essentials of the technic of ophthalmic nursing are carefully hidden away in the text, without any cohesion. The illustrations so necessary for this type of instruction are lacking, and the word pictures that might take their place are stilted in style. We may demand too much from our nurses in this country, but certain it is that an American nurse could not go far on what she might learn from this pamphlet. On the other hand, instructions are contained in this book for the dressing of patients after operation for cataract, a procedure that is always carried out here by the surgeon or one of his medical assistants. Taken by and large, it is difficult to see any great sphere of usefulness for this book in this country.

Allergy, Asthma, Hay Fever, Urticaria and Allied Manifestations of Reaction. By William W. Duke, Ph.B., M.D. Cloth. Price, $5.50. Pp. 339, with 75 illustrations. St. Louis: C. V. Mosby Company, 1925.

The author concerns himself only with the clinical side of the subject, using chiefly quotations for its purely theoretical aspects. This feature, frankly admitted by the author, constitutes the weakness and strength of the book. The author utilizes a great deal of practical experience in a disease which he finds to some degree present in as many as 15 per cent. of subjects. This is important, since the manifestations of allergy are apt to produce particularly disagreeable symptoms and are accessible to treatment, if interpreted correctly. Unfortunately, too much stress is put on too exact diagnosis, which the average patient cannot afford, and too little on nonspecific treatment, which is and will have to remain in the hands of general practitioners. Nonspecific treatment is essential for immediate relief, as well as for those cases that yield to it. The specific tests may be negative because of inherent defects of biologic tests or because it is impossible to test for everything. A better outline of treatment, with emphasis on the nonspecific agents, would be valuable. A chapter on anaphylactoid reactions caused by physical agents makes an original and interesting contribution to the subject.

The Normal Diet. A Simple Statement of the Fundamental Principles of Diet for the Mutual Use of Physicians and Patients. By W. D. Sansum, M.S., M.D., Director of the Potter Metabolic Clinic, Department of Metabolism, Santa Barbara Cottage Hospital. Cloth. Price, $1.50. Pp. 72, with 1 illustration. St. Louis: C. V. Mosby Company, 1925.

This, as the subtitle indicates, is a statement of the fundamental principles of diet for the mutual use of physicians and patients. As a statement of principles for physicians, it leaves nothing to be desired; it is interestingly written and easily read. We fail to see how it can be of great service to patients. They cannot well separate principles from practice; for them a book on normal diet should contain instructions on how to construct such a diet. A simple statement of principles is of little practical assistance to the patient.

Sonderband zu "Strahlentherapie." Herausgegeben von Prof. Dr. W. Fälta, Prof. Dr. C. J. Gauss, Prof. Dr. Hans Mayer und Prof. Dr. R. Werner. Band IX. Physikalische und technische Grundlagen der Röntgentherapie. Von Dipl.-Ing. Dr. Phil. G. Grossmann. Paper. Price, 13.50 marks. Pp. 300, with 207 illustrations. Berlin: Urban & Schwarzenberg, 1925.

This is devoted to a discussion of the application of roentgen rays to therapeutic purposes. In order to supply the demands of the roentgen-ray therapeutist, as well as those of the scientific investigator, all the accepted theories and their influence on the practice of roentgen-ray therapy are thoroughly discussed according to the best and latest information obtainable. Although some of the intricacies of theory may be beyond the understanding of the practicing roentgenologist, he is supplied at the end of each chapter with a summary of all the practical deductions. Particular stress is laid on the explanation of the theory concerning the absorption of the energy of the roentgen rays. The production of roentgen rays and all the subsequent phenomena are explained by the basic fundamentals of the electron-ether theories, the transformation of the bulk of electronic motion into caloric energy incidentally being mentioned. The concepts of wave length, tension within the tube and the periodicity of the roentgen-ray oscillations also are thoroughly explained. A special chapter is devoted to the discussion of filtration of roentgen rays. In dealing with the biologic action of the rays on living tissues, the author calls attention to the fact that one must distinguish between immediate and remote affects. The chapter dealing with dosimetric problems is particularly instructive, stress being laid on the principal points governing the construction of the various tubes and apparatus. The usefulness of this chapter is enhanced by a wealth of practical suggestions, covering not only all the details of employment but also the methods of preserving a stable function and the correction of occasionally occurring deficiencies. The protection of the patient and the operator is clearly defined. This book is a reliable guide for the practicing roentgenologist and a valuable reference book for the investigating and constructing electrician.

Parasitology for Medical Students. By Alex. Mills Kennedy, M.D., Professor of Medicine, University of Wales. Cloth. Price, $3. Pp. 142, with 62 illustrations. New York: Oxford University Press, 1925.

Within brief compass, the author has sought to present to medical students the essential features of parasitology for use in clinical study. One short chapter is devoted to each of the major groups of animal and plant parasites. The introductory matter in these chapters is hardly well put and might properly be omitted, as every one today has available some good textbook on zoology. A marked lack of balance appears in the selection of material. Thus, among flukes *Fasciola hepatica* is given more than two pages, whereas *Clonorchis sinensis* gets only brief mention, and *Paragonimus* and *Fasciolopsis* are not mentioned. The first named species is rare as a human parasite, whereas the others are all of first importance. The only strongyle mentioned is the hookworm, though several others are of real if not equal significance. Among the protozoa also, important forms are omitted, whereas others are treated over fully. There is no excuse today for using such names as *Distomum sinense* or *Taenia mediocanellata*. The colored plate is very successful, and the illustrations of insects are good. Most of those on parasitic worms are poor. The idea of the author, and the form in which it is presented, is good, but unfortunately the execution of the plan is much less successful. Perhaps there may be a reason in an English publication for giving awkward fractions, such as 1/6 and 1/25 inch, and yet one wonders how many microscopists today really can use them.

Mother's Manual. The Coming and Care of the Baby. By Dorothy Bocker, A.M., M.D., Instructor of Physical Education at Columbia University. Cloth. Price, $2. Pp. 247, with illustrations. New York: Brentano's, 1925.

This little volume contains the usual amount of information to guide young mothers through their pregnancy and to direct them in the care of the infant. The book is well illustrated, and there is even a diagram entitled "Spanking the Baby." This is intended, of course, to illustrate a method of resuscitation immediately after birth. One may well imagine that a great deal of time and effort was spent in preparing the anatomic and physiologic portions of this book, though it really seems time wasted to attempt to inform the busy mother about these subjects. What she needs is dogmatic directions about the care, feeding, bathing and airing of her baby. We are continually surprised by the fecundity of this variety of book. Would that it were possible for some legislative body or national academy to take a census of the actual number of these books already in existence in the English language, so that a new society for the regulation of birth control might limit the ever increasing supply of them.

A Short Key to Both Sexes of the Anopheline Species of India, Ceylon and Malaya. By C. Strickland, M.A., B.Ch., Professor of Medical Entomology in the School of Tropical Medicine, Calcutta. Boards. Price, Re. 1/12. Pp. 19, with illustrations. Calcutta: Thacker, Spink & Co., 1925.

The importance of identifying mosquitoes correctly is so evident in public health work that all aids will be welcomed in a task that at best is difficult. Strickland's key is admirable. The book is concise, well arranged and illustrated with great skill. One rarely finds so successful an effort to place highly technical data at the command of those who need it but are not trained in the particular field.

Medicolegal

Practicing Medicine—Treatment of Disease—Evidence

(Wideman v. State (Ala.), 104 So. R. 438. Ex parte Wideman (Ala.), 104, So. R. 440)

The Court of Appeals of Alabama holds, in *Wideman* v. *State*, that it was not necessary to aver that the defendant (Wideman) treated human diseases by a "system of treatment." It was sufficient to aver that he treated or offered to treat diseases of human beings without first having obtained a license from the state board of medical examiners. One who treats, or offers to treat, diseases of human beings by the system known as "chiropractic" or as "osteopathy" or by any system of medicine in any of its branches or departments, as a profession and means of livelihood, without first having obtained a certificate of qualification from the state board of medical examiners, is "practicing medicine" within the meaning of the statute, and may be found guilty of "practicing medicine without having first obtained a certificate of qualification, etc." While each treatment constitutes a separate offense, numerous treatments by one holding himself out to the public as a practitioner of chiropractic constitute "practicing medicine" as those words are construed in *Bragg* v. *State*, 134 Ala. 165, 32 So. 767. Evidence of many treatments of the same person was permissible under a count of an indictment charging "practicing medicine." But the state may be required to elect for which treatment it prosecutes under a count of an indictment charging that the defendant did treat, or offer to treat, diseases of human beings without having obtained a certificate of qualification from the state board of medical examiners. Under such count, evidence of more than one treatment is admissible, if limited to the purpose of showing the guilty knowledge of the defendant in administering the treatment for which the state elects to prosecute. It was competent for the state to show that the defendant had offices in Montgomery and had a sign "Chiropractor" over the door. It was also competent for the state to show that the defendant treated the prosecuting witness "for sickness." But it was not competent for the state to prove, over the defendant's objection, that the prosecuting witness paid the defendant for the treatments administered to her by him or what the defendant's charges for such treatments were, unless this was shown to be of the res gestae (essential circumstances) of the treatment. Admitting, however, that technical error was committed in this last respect, still, as the state was, on the undisputed evidence, entitled to a conviction and the penalty imposed was the smallest fine provided by the statute, no injury could possibly have come to the defendant's cause by reason of the admission of evidence that the prosecuting witness paid the defendant for the treatments administered to her by him or what his charges for such treatments were, and the judgment of conviction of practicing medicine without a certificate of qualification is affirmed.

In *ex parte Wideman*, the Supreme Court of Alabama, in denying, on rehearing, a writ of certiorari to review the judgment of the court of appeals, says that it thinks it quite clear that the language of the present statute punishing "any person who treats or offers to treat diseases" was advisedly substituted for the language of the former statute punishing "any person who practices medicine or surgery," etc., in the light of the decision in *Bragg* v. *State*, the purpose being, by the use of a comprehensive and well understood phrase, to foreclose such evasive contentions as the one made in that case. The treatment of disease comprehends diagnosis and the prescription or application of remedies for its alleviation or cure. Besides the allopathic and homeopathic schools of medicine, both of which employ drugs in the treatment of disease, there are a number of drugless systems, such as osteopathy, hydropathy, electrotherapy, thermotherapy, psychotherapy and chiropractic. Manifestly, the phraseology of the present statute is designed to place under the regulation prescribed all those systems for the treatment of human diseases, as well as any other system that may be conceived. The offense denounced is treating, or offering to treat, human diseases without a certificate of qualification from the state board of medical examiners. The phrase "by any system of treatment whatsoever" is no part of the description of the offense. Certainly we cannot impute to the legislature the utterly irrational and destructive purpose of turning loose on the people of the state a horde of ignorant charlatans and quacks, to practice medicine as they please, so long as they are able to show that they use no system. Such practitioners would be far more dangerous than those who are intelligent and skilful enough to follow some system of treatment. The statute does not prohibit a merely casual and friendly service. The indictment in this case was sufficient without alleging, either generally or specifically, that the defendant used a system of treatment, and a demurrer on that ground was properly held to be without merit.

Sufficient Identification of Roentgenograms

(Greco v. Schmidt (N. J.), 129 Atl. R. 146)

The Court of Errors and Appeals of New Jersey says that in this action to recover for personal injuries to a child run down by a truck the defendant contended that the trial judge had improperly admitted in evidence roentgen-ray plates showing the character of the child's injury. This objection was based on the fact that the physician who produced the plates at the trial had not himself taken them. The plates, however, were taken by another physician, under the supervision of the one who testified, and at a hospital at which the witness was engaged in professional work, and to which the child was taken. The rule is, as laid down in the case of *Robinson* v. *Payne*, 122 Atl. 882, that if the correctness of roentgen-ray photographs is established by the testimony of the person making them, or if they are identified by the surgeon under whose general direction and for whose use they were made, and by whom they were used in his diagnosis of the bodily injury, they are admissible in evidence. This court is therefore of the opinion that the roentgen-ray photographs were properly admitted in evidence, as they were identified by the physician at the hospital to which the child was taken, and were made under his supervision and direction, and for his diagnosis of the injury.

Legal Remedy After Performing Services for Minor

(In re Dzwonkiewicz's Estate (Mich.), 203 N. W. R. 671)

The Supreme Court of Michigan says that a physician performed a surgical operation on, and attended for about five months, a minor who was seriously injured in an automobile accident. The minor's father had abandoned his family. The mother frequently met the physician at the hospital, but the question of compensation was not discussed with her. The probate court appointed her guardian of the minor, and she was paid $6,500, less attorneys' fees, in settlement of the claim for damages which she sought to recover against a company charged with responsibility for the accident. Then the physician filed a petition in the probate court, setting up the foregoing facts, and averring that the services rendered by him for the minor were of the value of $500, and that the guardian had sufficient funds in her hands to pay for such services. He asked for an order requiring payment by her. Proof was taken by the probate court. The charges were found to be reasonable, and an order was entered directing payment thereof by the guardian. That order was reviewed in the circuit court, which set aside the order of the probate court on the ground that the physician had "mistaken his remedy"; that he should have proceeded by suit against the guardian. The supreme court, however, holds otherwise, setting aside the order of the circuit court, and affirming that of the probate court. In doing so, the supreme court says that the services were performed by the physician without express contract for payment. The father had abandoned his family. There was no doubt that the minor was liable for the reasonable value of the services on an implied contract to pay therefor. Such services as were rendered by the physician were "necessaries," within the meaning of that term as applied to the liability of infants to pay therefor. The right of the physician to recover in this proceeding was dependent on the implied contract of the ward to pay him for his services. He had no contract with the guardian. The proceeding to obtain allowance of the claim was akin to that of a creditor with a claim against the estate of a person deceased. There is no more of a denial of the right to a jury trial in such a proceeding than in the allowance of claims against an estate by the probate court. In either case an appeal may be taken to the circuit court, where the liability and the amount thereof may be determined by the jury, if desired.

Power of Minors to Contract for Medical Services

(Aubel v. Sosso et al. (Calif.), 236 Pac. R. 319)

The District Court of Appeal of California, First District, Division 2, says that in this action by a minor suing by his guardian ad litem (for the litigation) to recover damages for injuries caused by being struck by an automobile, the defendants attacked the ruling of the trial court in allowing the question of special damages to be submitted to the jury. This attack was based on the theory that the father of the minor being legally liable to furnish his son with necessary medical attendance, no obligation attached to the son for those expenses and he was not, therefore, entitled to recover for the outlay in this action. It was also argued that if any recovery could be had for the medical attendance furnished to the son, it must be on the suit of the father alone. In support of their position, the defendants cited Sections 35-37 and 207 of the civil code of the state, and from these argued that a minor living with his parents is incapable of entering into a contract even for medical services. No authorities were cited in support of the position taken by the defendants, and from this court's reading of the sections it is satisfied that the civil code did not intend to place such limitations on the power of a minor. This court can see no reason to hold that merely because these sections of the code prohibit a minor from disaffirming a contract for necessaries when not living under the care of parent or guardian, he is thereby disabled from entering into a valid, though voidable, contract for such necessaries while living under the care of a parent or guardian. On the other hand, Section 207 indicates an intention contrary to that suggested by the defendants, because if a third person may, under that section, supply such necessaries and recover the reasonable value thereof from the parent, it is because the minor is legally qualified to contract for such necessaries with the third person. Therefore, without being cited to any authorities which support the propositions, this court is not prepared to hold that a minor may not make such a contract while living under the care of his parent or guardian. If the contract for such necessities on the part of the minor is valid, the fact that the obligation has been met by advancements on the part of the parent prior to the trial of the case is no defense to the recovery of special damages arising out of the defendant's negligence. Judgment for the plaintiff was affirmed, and a new hearing was denied by the Supreme Court of California.

Society Proceedings

COMING MEETINGS

American Pharmacological Society, Cleveland, Dec. 28-31. Dr. E. D. Brown, University of Minnesota, Minneapolis, Minn., Secretary.

American Physiological Society, Cleveland, Dec. 29-31. Dr. W. J. Meek, Science Hall, Madison, Wis., Secretary.

American Society for Experimental Pathology, Cleveland, Dec. 28-30. Dr. E. B. Krumbhaar, Philadelphia General Hospital, Philadelphia, Sec'y.

American Society of Biological Chemistry, Cleveland, Dec. 28-30. Dr. D. W. Wilson, University of Pennsylvania School of Medicine, Philadelphia, Secretary.

Federation of American Societies for Experimental Biology, Cleveland, Dec. 29-31. Dr. Walter J. Meek, Science Hall, Madison, Wis., Sec'y.

Isthmian Canal Zone, Medical Association of, Ancon, Jan. 19. Dr. David L. Robeson, Ancon Hospital, Ancon, Secretary..

Sioux Valley Medical Association, Sioux City, Iowa, Jan. 19-20. Dr. R. F. Bellaire, Trimble Block, Sioux City, Secretary.

Society of American Bacteriologists, Madison, Wis., Dec. 29-31. Dr. James M. Sherman, Cornell University, Ithaca, N. Y., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal for a period of three days. No foreign journals are available prior to 1920, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Annals of Surgery, Philadelphia

82: 673-832 (Nov.) 1925

Epithelial Hyperplasia of Breast. G. L. Cheatle, London, Eng.—p. 637.
*Acute Hypotension of Cerebrospinal Fluid Following Cranial Traumatism. E. Stultz and P. Stricker, Strasbourg, France.—p. 678.
End-Results in Neurosurgery. W. Sharpe, New York.—p. 684.
*Surgical Treatment of Epilepsia Partialis Continua (Kojevnickovi). N. J. Beresnegovski, Tomsk, Siberia.—p. 698.
*Periarterial Sympathectomy. I. Cohen, New York.—p. 704.
*Neoplasms of Blood-Lymph-Vascular System; Endotheliomas. D. S. Pulford, Jr., Rochester, Minn.—p. 710.
*Klippel-Feil Syndrome. T. P. Noble and J. M. Frawley, Rochester, Minn.—p. 728.
Horseshoe Kidney. D. N. Eisendrath, F. M. Phifer and H. B. Culver, Chicago.—p. 735.
*Nonparasitic Chyluria. A. A. Kutzmann, Los Angeles.—p. 765.
Mechanism of Acute Osteomyelitis. A. O. Wilensky, New York.—p. 781.

Treatment of Acute Hypotension of Cerebrospinal Fluid.—Stultz and Stricker assert that the rational treatment of acute hypotension of the cerebrospinal fluid is the intravenous injection of from 30 to 40 c.c. of distilled water. The method is at once easy and safe. It may be advisable, in order to secure a definitive result, to repeat the injection twice or more. Sometimes the pressure becomes only stabilized after two or three hypertensive injections. Three cases are cited.

Treatment of Partial Continuous Epilepsy.—This disease is met very often in the north of Siberia, while in Europe it is comparatively rare. Village inhabitants are chiefly attacked with it. Probably the cold climate of Siberia plays some part in the etiology. Young persons, not older than 30, are chiefly affected. Hereditary syphilis is often marked and alcoholism prevails. Recent syphilis usually is not found. The Wassermann test gives negative results. The main symptoms of Kojevnickovi's epilepsy are continual convulsions of particular groups of muscles, as, for example, convulsions confined to one of the limbs. In spite of the strenuous work of the muscles of the affected limb atrophy often occurs. The local convulsions periodically change into total convulsions of epilepsy. The treatments are (1) medical, by the administration of preparations of bromin or mercury, and (2) surgical, as a decompression operation and one for the removal of cortical centers. Beresnegovski reports eight cases.

Periarterial Sympathectomy.—Eleven cases are reported by Cohen. Seven were of arteriosclerotic origin, two were thrombo-angiitic, one was caused by a trophic ulcer, and one by an ulcer in a mild diabetic, perhaps on a thrombo-angiitic basis. Three patients were completely relieved of pain, one of whom, however, lived too short a time to determine the permanency of the relief and one subsequently lost several toes in which dry gangrene existed at the time of the sympathectomy. One of the thrombo-angiitic patients showed slight but only temporary improvement. The trophic ulcer patient was somewhat benefited. In the remaining six cases no benefit could be seen from the operation.

Tumors of Blood-Lymph-Vascular System. — Pulford reviews 200 cases of neoplasm of the blood-lymph-vascular system: 183 angiomas, nine angio-endotheliomas, and eight endotheliomas. The original hypotheses seem established as facts: blood-vascular and lymph-vascular angiomas, while usually benign, are potentially malignant endotheliomas. There is an intermediate stage between these two represented by the angio-endothelioma which is relatively benign but definitely malignant. Malignant endotheliomas of the blood-lymph-vascular system exist as a pathologic entity. Just as a malignant tumor of the skin is recognized as a squamous-cell epithelioma by its differentiation into horny, protective epithelium, so may certain of the blood-lymph-vascular tumors be recognized as endotheliomas by their differentiation into tumor blood vessels.

Klippel-Feil Syndrome.—Numerical reduction of the cervical vertebrae is a comparatively rare congenital anomaly, but undoubtedly is more common than the literature would lead one to believe. Noble and Frawley report two cases. The clinical appearances of patients with this anomaly are characteristic: shortening of the neck, low implantation of the hair and limitation of neck movements. The pathologic changes may vary from absence of one or two cervical vertebrae to complete absence of the whole cervical spine. The condition is not incompatible with long life.

Nonparasitic Chyluria.—A case of unilateral nonparasitic chyluria, associated with a perirenal abscess, is reported by Kutzmann. Treatment is empiric. The intravenous use of neo-arsphenamin and pelvic lavages with from 1 to 3 per cent. silver nitrate solution has given encouraging results. Kidney exploration and nephrectomy have been done in cases showing poor progression.

Biology of Ductless Glands. W. L. Shank, DeKalb.—p. 404.
Diagnosis of Exophthalmic Goiter and So-Called Toxic Goiter. W. L. Bowen, Peoria.—p. 408.

Exsanguination-Transfusion in Intestinal Intoxication.—Brown reports on the results obtained from the use of Bruce Robertson's exsanguination-transfusion in the treatment of septicemia and intoxications of 105 cases of acute intestinal intoxications. Fifty-eight were cured; of eighty cases of erysipelas sixty-four were cured. Four cases of malignant scarlet fever were exsanguinated with complete recovery in all. In several cases of septicemia, cure was effected. In fifty-three cases of severe burns, twenty-nine patients were cured. The method has been used in other conditions in which there appeared to exist a form of unknown toxemia and in which all previous methods of treatment were unsuccessful. Instances of improvement and cure were noted in cases of severe acidosis of unknown etiology, primary peritonitis, infectious diarrhea in which there is always an accompanying toxemia, and diabetic coma, while no apparent benefit was noted in cases of uremia, toxemia of intussusception and general peritonitis.

62: 449-560 (Nov.) 1925

*Brains with Total and Partial Lack of Corpus Callosum; Nature of Longitudinal Callosal Bundle. C. DeLange, Amsterdam.—p. 449.
Schizophrenia; Case. J. H. Cassidy, Washington, D. C.—p. 477.
Studies on Dementia Praecox. Conditions Which Might Have Affected Brain Before Onset of Disease. S. Kure and M. Shimoda, Tokyo.—p. 485.
*Etiology of Hydrocephalus. A. S. Maclaire, New York.—p. 498.

Absence of Corpus Callosum.—DeLange reports the case of a boy without a corpus callosum. The patient was born in asphyxia and did not increase in weight, though he was breast fed. The taking of the bottle in hospital often met with difficulties, because his breathing was oppressed then. The child's case resembled more or less a case of myxedema; he had the hard and harsh voice which is so characteristic of infants suffering from this disease. The forehead was very narrow and retreating; the temporal fossae were both sunken. Inspiration was somewhat difficult, as if there were an obstacle in the nasopharynx. Heart, lungs and abdomen were normal. The hands were somewhat in pronation and continually moving about (as if playing the piano). The child was slightly hypertonic. After taking the feeding bottle the child often became blue, not on the face, which generally kept its normal color, but on the rest of its head, which assumed a dark blue hue. The number of red corpuscles was 5,800,000; the Wassermann reaction was negative; the fundus oculi was normal. An examination of the skull by roentgen rays was also negative, as was the result of the urine examination. The child died of pneumonia. A detailed postmortem report is given. An extensive polygyria and the absence of the corpus callosum were striking.

Prenatal Cerebral Hemorrhage as Cause of Hydrocephalus.—In view of the fact that a hydrocephalus was present at the second examination eight weeks after birth, together with the absence of any such evidence at birth and an etiologic factor (hemorrhage), possible of producing adhesions, was present at the time of birth, Maclaire holds that it is logical to conclude that the incomplete absorption of the hemorrhage produced the organization residue, and the deposit of this new *formed tissue over the cortex and along the base of the* brain caused the development of the hydrocephalic condition in the course of eight weeks.

Journal of Pharmacology and Experimental Therapeutics, Baltimore

26: 259-324 (Nov.) 1925

Inactivation of Atropin Sulphate by Rabbit Serum. J. LaBarre, Edinburgh.—p. 259.
*Physiologic Action of Furane. E. M. Koch and M. H. Cahan, Chicago. —p. 281.
*Effect of Sodium Arsenite on Blood Sugar Concentration of Rabbit and Dog. H. B. van Dyke, Edinburgh.—p. 287.
Metabolism of Salicylic Acid. E. G. Holmes, Cambridge, England.—p. 297.
Skin Absorption of Certain Gases. D. C. Walton and M. G. Witherspoon, Washington, D. C.—p. 315.

Action of Furane.—From the experiments made by Koch and Cahan it is evident that while furane has some anesthetic and analgesic properties, its toxicity is so great as to eliminate it from consideration for practical use. It seems to be a general protoplasm poison, completely inhibiting the growth of yeast. When given by inhalation it causes convulsions, apparently due to stimulation of the motor centers in the medulla and cord. This is followed by paralysis of the respiratory center and asphyxia. When administered in small doses by mouth it has a corrosive, solvent effect on the mucosa, causing a copious watery secretion. There is an increased permeability of the blood vessels, frequently producing extensive hemorrhages. Injection of 1.5 c.c. into a 10 kg. dog caused immediate death with symptoms and postmortem changes similar to those seen in acute prussic acid poisoning. There is a marked hyperemic condition of the lungs, dilatation of the veins and a bright, cherry red color of the blood.

Effect of Sodium Arsenite on Blood Sugar.—Van Dyke shows that sodium arsenite, intravenously administered in doses considerably below the lethal, causes a distinct but variable hyperglycemia in the rabbit. Accompanying this hyperglycemia there is a reduction in the blood alkali reserve; there is no significant alteration in blood concentration as indicated by determinations of corpuscle volume or percentage of hemoglobin. The hyperglycemia still appears after bilateral splanchnotomy or right splanchnotomy and left suprarenalectomy. Sodium arsenite, therefore, acts peripherally in all probability by increasing hepatic glycogenolysis. The hyperglycemia may be checked or prevented by insulin. Intravenous injections of sodium arsenite in the dog cause a reduction in the whole blood alkali reserve often with a slight hyperglycemia.

Roentgen-Ray Consultations of Future. G. Bartlett, Schenectady, N. Y. —p. 439.

Radium and Roentgen-Ray Treatment of Round Cell Sarcoma.—Schreiner and Herger have obtained what is apparently a clinical healing in thirteen out of thirty-five cases of round cell sarcoma which had lasted for periods varying in time up to six years and three months. In one group of cases, irradiation has yielded startling primary results, but recurrences in other parts of the body and anemias have proved fatal in almost all the cases. In the lymphosarcomatosis cases it is far better to divide a definite amount of irradiation over a period of time, from one to two weeks, in order that the body dose be as small as possible. Roentgen rays and radium together, with arsenic medication, are the methods of choice in the treatment of round cell sarcoma.

Cause of Death in Granulomas.—The terminus of these cases, Soiland says, is nearly always found in the deep abdominal glands where the pathologic change becomes firmly entrenched and resistant to any therapeutic attack. It appears that one may successfully destroy the altered lymph nodes in every part of the economy, even including those of the mediastinum, but the glands in the abdominal cavity are the cause of death.

Treatment of Pneumonia in Children.—The observations made by Hoppe and Freeman on the effect of mercurochrome-220 soluble on pneumonia are based on a series of forty-six cases, of which twenty-three were bronchial and twenty-three lobar in type. In these forty-six cases, twenty-three patients received mercurochrome and twenty-three were used as controls. Of the twenty-three controls, the average duration of illness was 16.5 days, while with those receiving mercurochrome the average duration of illness was 6.5 days. In three of these, the crisis occurred on or before the third day. The twenty-three patients treated with mercurochrome were sick on an average of 2.25 days after the first dose was given. The mortality of the control group was 39 per cent. Of those treated with mercurochrome, the mortality was 8.5 per cent.

Sinus Disease Simulates Brain Lesions.—Stuart is of the opinion that disease of the posterior ethmoid cells and sphenoidal sinuses at times produces signs and symptoms closely simulating those of organic brain disturbances, especially tumors and epidemic encephalitis. Whether or not this simulation occurs depends on the anatomic relations of the sinuses in question.

Sprue in Section of South.—Lewis' observation has been that there is a large proportion of sprue in the South and that it is not restricted by any degree of latitude. It is probably greatly confused with pellagra and, on account of a definite element of transmissibility, warrants the most careful study. Its principal features involve perverted intestinal digestion, possibly associated with a monilia. This digestive disturbance has, in Lewis' experience, been greatly improved by the feeding of bile salts.

Milk Sickness.—Six cases are reported by Wilkinson. The most striking feature of the clinical picture is the acidosis. The treatment of this single feature, with glucose in the form of molasses, has given prompt relief from the acute intoxication.

Screw Worms in Soft Palate.—In Gaudet's patient, examination of the throat revealed the soft palate to be very much swollen, with a perforation through the central part extending clear through, about the size of a 25 cent piece. This perforation was filled with worms burrowing in every direction into the tissues. Careful examination of the nose showed no worms at all in the nasal cavity at the time, though repeated examinations were made. Sixty-two worms were extracted.

*Rotunda Lying-In Hospital Report for 1923-1924. G. Fitzgibbon, R. M. Corbet and N. M. Falkiner.—p. 337.

Maternity Work in Rotunda Lying-In Hospital.—During the year 1923-1924, 1,973 patients were admitted to the Rotunda Lying-In Hospital and 1,703 were confined. Normal vertex was the presentation in 1,498 deliveries. This includes all occipitoposterior positions which underwent normal rotation. Eighteen vertex presentations were finally delivered as persistent occipitoposterior. Face presentation, excluding anencephalus, occurred eight times. Transverse presentation, excluding multiple pregnancies, occurred in five cases. Compound presentations occurred four times. Breech was the primary presentation in fifty-one cases, besides occurring in one of twins on nine occasions. There were twenty cases of twin pregnancies and seventeen cases of prolapse of the cord. Forceps were applied for the delivery of 101 patients, seventy-eight primiparas and twenty-three multiparas. Version was performed thirty-one times. In four cases the fetus was broken up to effect delivery. Persistent primary uterine inertia was present in eight cases. There was only one case of definite contraction ring dystocia. Induction of labor was performed thirty times and induction of abortion or miscarriage seven times. Eight cases of accidental hemorrhage occurred. There were twelve cases of placenta praevia, seven cases of postpartum hemorrhage and three cases of rupture of the uterus. The placenta had to be removed manually nineteen times. There were 163 patients with external measurements considerably under normal. Internal pelvimetry was done only once as dependence was placed far more on the application of the head to the pelvic brim, as made out under anesthesia and by noting the progress of labor, than on the actual dimensions of the pelvis. Delivery was effected by cesarean section nineteen times; six patients had sections done previously; in two patients it was the third section. One patient was delivered by pubiotomy after thirty-six hours in labor, the head being impacted in the brim. In sixteen cases treatment was by induction of labor—eleven times for definite contraction of the pelvis and five for disproportion owing to the large size of the fetus. In 220 patients the urine was found to contain a marked amount of albumin. In three cases hyperemesis occurred. There were ten deaths in the intern department; the causes were: sepsis, rupture of a cesarean scar, rupture of the uterus during evacuation, and hemorrhage in a full term ectopic pregnancy, the patient dying just after laparotomy. One patient died of cardiac failure from myocarditis. In the extern department there were eleven deaths, making in the whole maternity service twenty-one deaths. Twelve patients were admitted on account of pain and were found to have pyelitis. There were three cases of hydatid mole; three cases of multiple fibroids of large size with pregnancy; one case of chorea; four cases of mania and one of marked mental derangement for a few days after eclampsia; one case each of herpes, gallstones, appendicitis, anemia, erysipelas and thrombosis of the saphenous vein.

Liver in Umbilical Cord.—Hipsley reports the case of an infant seen twelve hours after birth that presented a spherical enlargement of the umbilical cord about 3 inches (7.5 cm.) in diameter in its widest portion. None of it was covered by skin. When this mass was opened, the liver was found within it. The liver was returned within the abdominal cavity. The infant made an uninterrupted recovery, and three weeks later appeared to be perfectly normal.

*The Diazo Reactions G Piotrowski—p 798

Clinical and Physiologic Study of Pancreatic Fistula.—Villaret and Justin-Besançon have had the opportunity to study for seven months and apply various tests to a fistula of the pancreatic duct, consecutive to a gastro-enterostomy, subtotal gastrectomy and exclusion of the pylorus, in a man, aged 43 The rhythm of the secretion of pancreatic juice appeared markedly changed, the assimilation of nitrogen, phosphorus and sulphur considerably reduced The internal secretory function of the pancreas appeared unaffected. The pancreatic juice did not contain invertin, trypsin production seemed normal or enhanced Insulin did not modify the secretion; the influence of atropin was indirect. Injection of magnesium sulphate into the jejunum provoked the appearance of bile, without stimulation of the pancreatic secretion The influence of hydrochloric acid was the reverse of this No tendency to a psychic pancreatic secretion could be detected The fistula did not improve spontaneously, nor heal under the action of insulin or atropin Only an operation restored the passage of pancreatic juice into the intestine

Technic for Dosage of Cholesterol in Duodenal Juice.—Chiray and his co-workers describe a simplified Grigaut method for clinical dosage of cholesterol in the duodenal juice, obtained by intubation. With this method, they say the colorimetric reading is easy and rapid The findings are sufficiently exact for clinical purposes

Mechanism of Diazo Reactions.—Piotrowski's study confirmed that the bilirubin in mechanical jaundice is identical with that in hemolytic jaundice. The direct diazo reaction depends on the presence of free bilirubin in the serum; the indirect, on association of bilirubin with the proteins of the plasma. The intensity of adsorption phenomena is connected with the amount of proteins and cholesterol in the blood Doubt is expressed as to the diagnostic value of the diazo reaction in dubious cases

*The Blood Pressure in Aviators R Cruchet—p 1489

Influence on the Blood Pressure of Variations in Atmospheric Pressure.—Cruchet reiterates that under the low air pressure at high altitudes, the arterial pressure in the flyers increases. The pressure becomes normal and all other phenomena of flight sickness disappear as soon as oxygen is regularly inhaled. He asserts that the influence of oxygen is still manifest at an altitude of 8,000 meters, and probably even higher. Even the untrained can bear without harm an air pressure corresponding to an altitude of 8,000 meters if they inhale oxygen regularly. He gives charts showing the regular rise and fall of the blood pressure above and below normal as the atmospheric pressure in the air chamber was varied to correspond to very high altitudes or sea level

Susceptibility of the Skin to Roentgen Rays in Various Diseases.—Neu's investigation indicated that an exaggeration of this susceptibility was most pronounced in exophthalmic goiter; less with tuberculous glands, and still less with fibroma. In exophthalmic goiter, the fact may be partly ascribed to a general irritability of the vessels; in the other affections, neither anemia nor hyperemia of the skin can be incriminated. The factor modifying the skin susceptibility is still a mystery.

Alveolar Pyorrhea. O. Muller.—p. 1055. C'td.

Cow's Milk and Infants.—The experiences of the last ten years have convinced Feer that the 600 c.c. of cow's milk he had recommended for infants in 1916 is still too much. He does not give more than 500 c c daily. He recommends 100 gm per kilogram of body weight up to the amount mentioned, and adds water, sugar, flour and, after the sixth month, thin gruel, soup, vegetables, fruits, later zwieback and bread crust Fresh fruit juice (teaspoonful) may be given even as early as in the fourth month. He reduces the milk in the second year to 400 c.c. and later to 200-300 c.c. daily. Sometimes it is better to avoid it entirely, especially with anemia Two diet lists for children are suggested

Living Cysticercus Racemosus Found in Brain at Decompressive Operation M Alurralde and M J. Sepich—p. 65.
Acute Delirium with Purulent Stomatitis; Two New Cases Nerio Rojas and J C Belbey—p 77.

Nocturnal Trigeminal Neuralgia.—The neuralgia had been constantly recurring for fifteen months, almost exclusively during sleep Obarrio has found insufficiency of the liver in all such oneiric disturbances, and cures them promptly by a nontoxic diet, supplemented by a glass at each meal of a solution of 10 gm of sodium sulphate, 5 gm of sodium phosphate and 5 gm of sodium bicarbonate in 1 liter of water. The oneiric neuralgia or delirium appears when digestion has reached the peak of absorption from the intestine, with the liver function and the elimination of carbon dioxid at their lowest point. He sometimes gives peptone in addition; this alone cured the nocturnal neuralgia in a case reported in the *Presse medicale* in 1922.

Antibacteriophage Action of Human Serum.—Katsu found a strictly specific antibacteriophage action in a serum which agglutinated the Flexner type of dysentery bacilli. A similar action was observed in three other serums which also agglutinated these bacilli. Treatment of the serum with the bacilli did not diminish its antibacteriophage action. He agrees with Sonnenschein that the method might prove valuable in diagnosis

Prognosis of Genuine Nephrosis.—Steinitz reports an instance of complete recovery from grave genuine nephrosis (nephritis with edema without hypertension or hematuria). The boy, 11 years old, recovered under treatment with large doses of urea (up to 100 gm. daily), and is healthy at present, eight years after the disease

Urea in Saliva as Kidney Function Test.—Simmel and Kuntscher confirm the practical value of Hench and Aldrich's salivary urea index.

Research on Gastric Secretion.—Katsch and Kalk found in caffein (0.2 gm. of pure caffein in 300 gm. of water) an almost equally good substitute for the alcohol test meal.

Formation of Iron Salt in Differentiation of Tissues.—Christeller and Kaiser treated fresh tissues with iron salts and later with hydrochloric acid and potassium ferrocyanid. The cytoplasm of epithelial cells—especially cancer cells—but also the muscles accepted the iron. They point to a possibility that the presence of lactic acid plays a rôle.

Sleep.—Heilig and Hoff found a "vagotonic" blood pressure reaction to epinephrin during sleep; the alimentary glycemia is higher in normal and paraldehyd sleep. The cerebrospinal fluid contains more sugar and protein, less chlorids. The blood from sleeping persons lowered the number of drops in the Läwen-Trendelenburg frog preparation much less than the blood from the same subjects when awake.

Oxydases of Leukocytes.—Mielke believes that Graham's distinction of four types of neutrophils according to the number of granules containing a peroxidase is based only on technical errors.

Conduction in Cerebrospinal Fluid.—The electric conductivity of cerebrospinal fluids in Schaefer's determinations averaged $1.49 . 10^{-2}$. The extreme figures were $1.05 . 10^{-2}$ and $2.00 . 10^{-2}$.

Function Test of Reticulo-Endothelial System.—Memmesheimer and Klövekorn injected intravenously a fine emulsion of oil, and examined blood smears with the dark field illuminator. The droplets disappeared very slowly in patients with secondary syphilis—especially those under arsphenamin-bismuth treatment. The injection induced a shock in some patients, in whom a rapid disappearance of the fat had been observed.

Stomach Tube and Mechanical Stimulus.—Hirschberg and Ganskau do not believe in the mechanical provocation of gastric secretion. It is only a continuation of the secretion which had been going on before the tube was introduced. It is simply the well known psychic secretion, caused usually by the observation of the breakfast being taken by others in the room. This fasting secretion stops after injection of atropin. A digestive secretion continues in spite of it.

Constancy of Gas Metabolism.—Reiss and Weiss determined the oxygen consumption in mice and rats in twenty-four hour periods. The animals were allowed to move about and eat. The oxygen intake was remarkably constant (± 5 per cent.).

Suprarenals After Insulin.—Poll examined the suprarenal glands in various animals after injections of insulin. He found hyperemia, changes of distribution of lipoids, and loss of chromaffine substance. The latter could be prevented by injections of epinephrin.

The Colon Problem.—Pendl administers at least half a tablespoonful of castor oil for ten days after sutures of the colon. It keeps the contents fluid, and thus avoids the tension of gas behind hard scybala. He lost two out of thirty-seven patients.

Treatment of Enuresis.—Freud applied ethyl chlorid to freeze the skin covering the sacral bone or above the symphysis. He reports excellent results after one or two such procedures. Freezing the chest or back was of no value.

Lactation and Submammary Temperature.—Moll observed in lactation a higher temperature in the skin fold below the breast than in the axilla. It is almost as high as the rectal temperature. It is a good indicator of the ability to produce milk.

Complexion in Pyuric Infants.—Lasch, Fischer and Silber found an increased bilirubin concentration in the serum of four of twelve cases of pyuria in infants. These four infants presented the peculiar pale yellowish complexion which is known as a sign of the disease. It is the expression of a septic jaundice.

Public Health Service in Bavaria. Seiffert.—p. 1976

Athletic Training.—Ewig found a moderate dilatation of the heart in persons training for various sports. This increases the length of the muscle fibers and the energy of their contraction. A hypertrophy was found, instead, in a few cases. An increased amplitude of the blood pressure, and bradycardia were confirmed. Aschner's eyeball compression test, the carotid pressure test, and Erben's test gave about the same results as in persons not under training. Examinations of the blood for changes of the calcium and potassium content revealed hardly any difference, but Chvostek's phenomenon was present in over one half of the athletes (against one third of the controls). The alkali reserve of the blood increased.

Serodiagnosis of Cancer.—Bott confirms the good results with Wigand's tannin test. Yet it is negative with beginning cancer.

Hutchinson's Triad and the Endocrines.—Cedercreutz has collected the evidence which might speak for the possible endocrine genesis of Hutchinson's teeth, parenchymatous keratitis and the typical affection of the labyrinth. The congenital syphilis might attack primarily the endocrine glands.

Urobilin in Cirrhosis of the Liver.—Lichtenstein, using Terwen's method, found a high ratio between the urobilin excreted in the urine and that contained in the feces in cirrhosis of the liver. The elimination by way of the urine is also considerable in pernicious anemia or hemolytic jaundice, but the amount in the feces is much larger.

Sympathicotonus of Brain Arteries in Pregnancy.—Muck observed in many pregnant women prolonged white marks on the mucous membrane of the nose when irritating it with a sound after application of epinephrin. He regards this as a sign of increased sympathetic tonus of the arteries of the head—especially of the brain.

Liver Function Tests.—Fischler reviews the recent additions to the knowledge of the functions of the liver. He pleads for a routine examination of urine for urobilin, which reveals a concomitant disease of the liver as often as the test for albumin reveals disease in the kidney. Starvation as well as one-sided diets injure the liver. The empiric diet for gout—little protein and fat and moderation in general—is the best rest cure for the liver. Intravenous injections of glucose should not be forgotten in acute grave disturbances of the liver (acute atrophy, mushroom poisoning).

Surgical Mistakes of Practitioners. Schnitzler. Supplement.—pp. 1-24.

The Motor and Secretory Function of the Stomach.—Hess and Faltitschek found that patients with ulcers of the stomach show no change in the secretory or motor function of the stomach after paravertebral injection of 5-10 c.c. of a 1 per cent. solution of procain, made in the seventh thoracic segment. In healthy subjects and in gastric neuroses, the increase in both was constant. They believe that the lack of reaction in ulcer patients is due to an organic interruption of nerve conduction.

Insulin and Cholin.—Waltner found an increased susceptibility to cholin in animals during the insulin hypoglycemia.

Preparation of Vaccines.—Popper and Silberstein recommend quinin sulphate for preservation of vaccines.

Hemoclastic Crisis.—Altschuller considers the shifting of the leukocytes to the left (Arneth) as the most important sign of a true hemoclastic crisis in Widal's sense. He produced it by administration of sugar in diseases of the liver, as well as by Umber's method (milk by the rectum). No shifting was observed in the refractory phase following administration of milk, or after an enema consisting of water.

Tuberculosis of the Placenta.—Horálek found tuberculous nodes in the placenta of a woman who died two months after a normal delivery. The child was 5 months old at the time of the report, and developing normally.

Hospitalstidende, Copenhagen

68: 953-968 (Oct. 15) 1925

*Skin in Surgical Affections. J. Ipsen. Begun, p. 944.

Temperature of the Skin in Surgical Affections.—Ipsen describes his technic for recording the temperature of the skin under a layer of felt, and charts the findings under various conditions. Abnormally high temperatures at certain points, revealed by this technic, aid in differential diagnosis between loose bodies in joints or laceration of a semilunar cartilage and inflammatory processes, for example. The local temperature was exceptionally high with a sarcoma in the knee and with mammary cancers. The findings were not instructive in peritonitis.

Ugeskrift for Læger, Copenhagen

87: 881-904 (Oct. 8) 1925

*Transformation of Glycogen. Lundsgaard and Holbøll.—p. 881.
*Treatment of Genital Gangrene. O. Jersild.—p. 884.
*Schick Reaction in Greenland. E. Bay-Schmidt.—p. 889.
Analysis of Breads. H. Kærn.—p. 889.

Transformation of the Liver Glycogen Into Glucose.—Lundsgaard and Holbøll report research which shows that the glycogen in fresh and finely chopped liver tissue is split into alpha-beta glucose. Insulin does not affect this cleavage. They assume that in the living subject the glycogen undergoes the same transformation. The carbohydrates under the action of insulin are partly oxidized and partly deposited as glycogen. When the insulin is no longer in the blood, the deposits of glycogen are split into glucose, which explains the higher sugar content of the blood in the morning. Is the new glucose—ny glucose, as they call the kind with a lower specific rotating power—an intermediate link in the production and depositing of glycogen?

Neo-Arsphenamin in Treatment of Genital Gangrene.—Jersild gave the drug by the vein, in his twelve cases, and states that the effect on the temperature and the course of the process was so prompt and so constant that this treatment should be given at once in every case, regardless of the temperature or general symptoms.

The Schick Reaction in Eskimos.—Bay-Schmidt relates that a strongly positive reaction was obtained in an average of 68 per cent. of 382 persons in the isolated colony of Julianehaab. A dubious response was obtained in all the others, none giving a decidedly negative reaction. Diphtheria has appeared only once in the colony (1921) and soon died out, attacking only thirty young persons.

87: 905-922 (Oct. 15) 1925

*Action of Liver Tissue on Glucose. Lundsgaard and Holbøll.—p. 905.
Vaccine Therapy of Suppurative Colitis. A. Borghjærg.—p. 909.
Case of Epiploitis Tumefaciens. E. Holm.—p. 912.
Fight Against Rural Tuberculosis. Kjer-Petersen.—p. 914.

Action of Liver Tissue and Insulin on Glucose in Vitro.—Lundsgaard and Holbøll conclude from their latest research that the liver serves in carbohydrate metabolism as a storage place for glucose in the form of glycogen, and has no direct importance for the metabolism of glucose in the organism. Contrary to muscle tissue, liver tissue is not able to form new glucose out of alpha-beta glucose under the influence of insulin.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER 1925

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. *Two journals may be borrowed at a time.* No foreign journals are available prior to 1920, nor domestic journals prior to 1923. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Thus most of these journals are accessible to the general practitioner, no matter where located.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an original article in THE JOURNAL

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D" and "S" State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association" The name of the author, in brackets, follows the subject entry.

For author index see page 2110.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL In the Current Medical Literature Department only the articles which have been abstracted are indexed

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "Ml," Medicolegal; "P," Propaganda for Reform, "ME," Medical Economics, "ab," abstract, the star (*) indicates an original article in THE JOURNAL

This is a subject index and one should, therefore, look for the subject word, with the following exceptions "Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D" and "S" State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association" The name of the author, in brackets, follows the subject entry.

For author index see page 2110.
